Latest version: <https://yungyutsai.github.io/papers/EndowmentTax.pdf>

Abstract

A select few non-profit colleges in the US have managed enormous endowments that annually generate considerable capital gains which have been historically tax-exempt. The 2017 Tax Cuts and Jobs Act introduced a net investment income tax that targeted these colleges to enhance tax equity and wealth distribution within higher education. This paper examines colleges' behavioral responses and their effects on educational access. Findings reveal that taxed colleges increased tuition, shifting the burden to students and reducing college access to historically underserved groups. Conversely, colleges that can maneuver around the tax, increase their enrollment to circumvent the enrollment-related tax threshold, thereby creating more educational opportunities despite revenue losses. These findings underscore the potential for policy design to guide institutional responses to taxation in ways that benefit society.

1 Introduction

A small number of selective private non-profit colleges in the United States manage substantial endowments that generate considerable capital gains, which have historically been tax-exempt (Sherlock et al., 2018; Quinn, 2019; Bird-Pollan, 2021). Scholars and policymakers have noted that this wealth is disproportionately concentrated and often used for accumulation rather than educational purposes (Frey, 2002; Cowan, 2007; Nichols & Santos, 2016), questioning the justification for tax exemption. In response, the 2017 Tax Cuts and Jobs Act (TCJA) introduced the Net Investment Income Tax (NIIT) — a 1.4% excise tax — on these nonprofit colleges’ investment returns.¹ However, affected colleges argue the tax burden may reduce their ability to support education and financial aid.² Concerns also exist about potential system gaming, as colleges might manipulate their enrollment or endowment sizes to avoid the tax, potentially decreasing educational resources (Fishman, 2018; Hinrichs, 2018).

This paper evaluates nonprofit colleges’ behavioral and fiscal responses to the NIIT. Specifically, I examine whether and to what extent colleges manipulate their enrollment or assets to avoid the tax. The study also investigates whether taxed colleges adjusted tuition, reduced financial aid, or cut other spending to offset the tax burden. A key focus of the analysis is how these institutional responses affect the access and distribution of educational opportunities. Through this comprehensive analysis, the paper assesses the consequences of colleges’ behavioral responses on tax revenue (or losses), access to higher education, and broader societal benefits (or costs).

I combine data from the Integrated Postsecondary Education Data System (IPEDS) and Internal Revenue Service (IRS) Form 990 data, tracking colleges from 2010 to 2022. Using a difference-in-differences (DD) framework, I evaluate two types of institutional responses: tax avoidance (attempts to maintain tax-exempt status) and cost-shifting behaviors (paying taxes while transferring the burden to others). Additionally, I examine how these responses affect the distribution of college

¹This tax only applies to colleges with more than 500 students and more than \$500,000 in assets per student.

²In March 2018, 48 colleges wrote a joint letter to Congress to raise this concern. Retrieved Jan 10, 2023, from https://ofr.harvard.edu/files/ofr/files/march_2018_endowment_tax_letter_to_leadership_from_schools.pdf.

enrollment opportunities. To complement the DD analysis, I employ the synthetic control method (SCM) to evaluate individual colleges' responses regarding taxes paid or avoided and costs shifted to students, comparing these outcomes to government revenue to assess overall societal impacts.

The analysis reveals that nonprofit colleges engage in both tax avoidance and cost-shifting behaviors. Colleges near the tax threshold increase student enrollment to circumvent the assets-per-student requirement, effectively avoiding the tax. While this behavior reduces government revenue, it creates additional enrollment opportunities that benefit students across all backgrounds. In contrast, colleges that pay the tax respond by shifting the burden to students through increased tuition and charges. Of the total NIIT revenue of \$324 million annually, students bear \$287 million (88%) through higher tuition and room-and-board fees. Although colleges maintain their spending levels and enrollment numbers, the increased attendance costs alter student composition, reducing opportunities for historically underserved groups and middle-low-income students who rely on study loans. These findings suggest that while taxing nonprofits may generate government revenue, society ultimately bears the burden. However, well-designed incentives and policies could encourage nonprofits to increase their provision of public goods.

This study contributes to the broader debate on nonprofit tax exemptions, which represent significant forgone tax revenue.³ While nonprofits receive tax exemptions to provide public goods (Hassan et al., 2000; Stevens, 2010; Mayhew & Waymire, 2015; Zare et al., 2022), critics argue these benefits are not always used to enhance services (D. Zimmerman, 1991; Cowan, 2007; Nichols & Santos, 2016; Herring et al., 2018; Propheter, 2019a). This research advances this debate by providing empirical evidence on how taxation affects institutional behavior and societal outcomes.

The study makes two significant contributions to the literature on nonprofit taxation behaviors. First, it provides new insights into nonprofits' tax avoidance strategies. While previous research has examined revenue manipulation (St. Clair, 2016; Marx, 2018) and financial misreporting (Omer

³At the federal level, Brody & Cordes (2006) estimated the annual tax exemption for nonprofits at \$45 billion, accounting for 2% of federal tax revenue. At the state and local levels, Sherlock & Gravelle (2009) estimated annual tax exemptions for nonprofits range from \$31 to \$48 billion, roughly 2.4 to 3.7% of state and local tax revenues. For the higher education industry, Baum & Lee (2019) estimated the tax exemption for nonprofit colleges at \$22 billion.

& Yetman, 2007; Hofmann, 2007), these studies focused on organizations *reducing* their size or manipulating numbers without changing service levels. The NIIT context uniquely allows for examining scenarios where organizations might *expand* their services to avoid taxation, offering new insights into whether nonprofits prioritize output maximization over cost minimization.

Second, this research advances our understanding of nonprofits' tax-shifting behavior. Previous studies have investigated whether nonprofits reduce service levels in response to taxation (Grimm Jr, 1999; Fei et al., 2016; Herring et al., 2018), but little research exists on how taxation affects service delivery and pricing. This study fills this gap by documenting how colleges' tax-shifting behaviors redistribute access to public services through increased tuition and altered student demographics, even when overall service levels remain unchanged.

In a concurrent paper, Ryan et al. (2024) provides initial empirical evidence of colleges' responses to the NIIT, focusing on eight selected institutions using SCM for each single case. Their findings indicate that some colleges respond by increasing enrollment, raising attendance costs, or reducing financial aid.⁴ The present study expands this analysis by comprehensively evaluating the behavioral responses of all affected colleges and examining the broader impacts on educational opportunity and enrollment composition.

2 Policy Background

The 2017 TCJA imposed a new NIIT on nonprofit colleges with large endowments. According to the regulation, nonprofit colleges with more than 500 tuition-paying students and more than \$500,000 in assets per full-time equivalent (FTE) student would be subjected to a 1.4% excise tax on net investment income. Nonprofit colleges that do not meet the cutoffs and all public colleges remain exempted from this taxation.⁵ The policy went into effect on January 1st, 2018.

⁴Their estimation uses only three years (2015—2017) during the pre-intervention period, which might be insufficient for valid SCM projections (Abadie, 2021). Additionally, while they provide some descriptive statistics, they did not apply a formal DD analysis to examine the response of all affected colleges, limiting the understanding of the full picture of the policy impact.

⁵Public colleges are not subjected to the policy. Notably, none of the public colleges fully meet the tax thresholds. In contrast, for-profit colleges have always been subject to income tax, just as private firms are.

The tax threshold is based on student enrollment and asset size. However, the IRS leaves some discretion to colleges. Specifically, the IRS defines student size as “the daily average number of full-time students, with part-time students being taken into account on a full-time equivalent basis,” but it is up to colleges to decide how to convert part-time students into full-time equivalents. Additionally, the IRS defines assets as the “aggregate fair market value of assets” but allows colleges to use any reasonable method to evaluate their assets.⁶

The IRS initially estimated the tax would be applied to 25 to 40 colleges (ACE, 2019). In actuality, during the first year of the policy, 33 colleges were subjected to the tax. Table A1 in Appendix A lists the colleges potentially affected by the tax and their tax statuses from 2018 to 2022. As the taxation thresholds have not changed, the number of colleges subject to the tax would increase as institutions’ endowments grow. As of 2021, 40 colleges were affected by the tax.

Despite the good intention of the policy to address wealth inequalities and encourage colleges to invest resources for educational purposes rather than wealth accumulation (Cowan, 2007; Willie, 2012; Sherlock et al., 2018; Fishman, 2018), concerns have been raised about potential tax avoidance and cost-shifting. Firstly, as the tax applies only to colleges surpassing specified thresholds, scholars fear that colleges might manipulate their student or endowment sizes to avoid the tax, resulting in decreased available educational resources (Fishman, 2018; Hinrichs, 2018).

Secondly, many colleges stated that the policy could force them to shift the burden to students by cutting spending or raising tuition. In March 2018, 48 colleges wrote a joint letter to Congress stating that the new tax placed a significant burden on them and limited their ability to provide financial aid and support core educational activities.⁷ Individual colleges also delivered similar messages. For example, Stanford mentioned that the tax would harm their ability to provide financial aid and support academic mission (Selig, 2020), MIT asserted that the tax would constrain their expenditures toward scholarships, education, and research (Stendahl, 2017), and Trinity University stated that the tax bill would force them to increase tuition or cut aids (Derrig, 2017).

⁷Endowment Tax Letter to Leadership. Retrieved Jan 10, 2023, from https://ofr.harvard.edu/files/ofr/files/march_2018_endowment_tax_letter_to_leadership_from_schools.pdf.

Table A2 in Appendix A provides insightful statistics on the expenditures and revenues of colleges subject to the tax and offers a basis for estimating the expected tax bills derived from their net investment incomes. The estimated tax bills for the affected colleges, computed using a 1.4% tax rate, average \$13 million annually (ranging from \$1 million to nearly \$60 million). This figure accounts for 0.5% of total revenue (ranging from 0.04% to 1%) or 1.3% of total expenditures (ranging from 0.04% to 3%) for the institutions.

Although the current tax liability affects only a few colleges and appears minor relative to endowment size, several proposals seek to expand its scope and impact. Bill S.3514 proposes increasing the tax rate from 1.4% to 35% for colleges with endowments above \$10 billion.⁸ H.R.8883 suggests a 10% rate for colleges with per-student endowment assets above \$250,000, affecting over 150 institutions.⁹ Bill S.3465 proposes a one-time 6% tax on total endowment assets above \$9 billion.¹⁰ Evaluating the current policy's societal impact provides crucial insight for considering these alternative proposals.

3 Theoretical Framework and Literature Review

This section provides a theoretical framework for nonprofit colleges' responses to taxation and reviews literature on how nonprofits and colleges handle tax burdens and financial shocks. The analysis examines two primary responses: tax avoidance (attempts to maintain tax-exempt status) and cost-shifting (transferring the tax burden to others).

3.1 Tax Avoidance

Organizations may reduce tax liability through tax evasion, tax avoidance, or tax planning. Tax evasion involves *illegal* behaviors, while tax avoidance leverages gray areas or legal loopholes in the tax system (Slemrod & Yitzhaki, 2002; Onu et al., 2019). Tax planning, in contrast, utilizes legally designed provisions such as deductions or benefits (Onu et al., 2019).

⁸See <https://www.congress.gov/bill/118th-congress/senate-bill/3514> for details.

⁹See <https://www.congress.gov/bill/117th-congress/house-bill/8883> for details.

¹⁰See <https://www.congress.gov/bill/118th-congress/senate-bill/3465> for details.

This paper focuses specifically on tax avoidance behavior, particularly the manipulation of values to maneuver around tax thresholds. The NIIT structure is straightforward: a single-tier tax rate of 1.4% applies to nonprofit colleges meeting specific thresholds on their net investment income. Legal tax planning opportunities are limited since the tax allows few deductions beyond investment expenses. While tax evasion is possible, donor restrictions and transparency requirements on endowment returns make concealment difficult (Bowman, 2007; Dahiya & Yermack, 2018). Therefore, this paper concentrates on tax avoidance strategies related to maintaining tax-exempt status by managing threshold-related metrics.

Prior research indicated that nonprofit organizations respond to tax or regulatory thresholds by manipulating their financial variables (Sansing & Yetman, 2006; St. Clair, 2016; Marx, 2018). For example, St. Clair (2016) and Marx (2018) found nonprofits *reduce* their revenue to avoid the financial reporting or auditing requirement. Additionally, Sansing & Yetman (2006) discovered that private foundations increase their payout rate to qualify for a lower tax rate.

However, while for-profit entities often reduce reported asset values to avoid taxes (Hosono et al., 2018; Cespedes et al., 2021), nonprofits rarely do so (Marx, 2018), primarily due to donor restrictions (Surysekar et al., 2015; Hung & Berrett, 2021; Prentice & Clerkin, 2023) and the need for financial transparency (Keating & Frumkin, 2003; Calabrese, 2011; McDonald III & Goodman, 2021). Therefore, although the NIIT allows colleges to manipulate either asset values or student enrollment, enrollment adjustments are the more likely choice for tax avoidance.

3.2 Tax Shifting

Organizations may shift tax burdens through three mechanisms: reducing service *quantity* (cutting student enrollment), reducing service *quality* (decreasing instruction and research spending), or increasing service charges (raising tuition and fees). While price increases may not affect service delivery directly, they impact accessibility. This section examines how nonprofit colleges handle increased financial burdens by reviewing research on nonprofits' responses to taxation and colleges' responses to financial shocks.

3.2.1 Nonprofits' Tax Shifting Behaviors

The nonprofit hospital sector provides the closest parallel to higher education. Studies comparing nonprofit and for-profit hospitals' community service levels ([Rosenbaum et al., 2015](#); [Herring et al., 2018](#); [Propheter, 2019b](#); [Zare et al., 2022](#)) suggest that nonprofit hospitals maintain higher service levels regardless of tax exemption generosity. For instance, [Herring et al. \(2018\)](#) found that nonprofit hospitals consistently provide more community service than their for-profit counterparts, with this difference remaining stable across varying tax exemption levels.

Private foundations' responses to NIIT offer particularly relevant insights. [Sansing & Yetman \(2006\)](#) studied a dual tax rate system where foundations with endowment payout rates exceeding 5% qualified for a 1% rather than 2% tax rate on investment income. Their findings showed no significant differences in charitable spending or payroll between foundations just below and above the cutoff, suggesting that higher tax rates did not lead to service reductions.

Studies of property tax exemption variations ([Grimm Jr, 1999](#); [Fei et al., 2016](#)) found minimal to no impact on nonprofit activities. However, these studies focused primarily on revenue effects rather than examining changes in spending patterns or service delivery.

This literature suggests that nonprofits generally maintain service levels despite taxation, aligning with theories of nonprofit output maximization ([Brooks, 2005](#); [Chang & Jacobson, 2011](#)). However, existing studies have largely relied on spending or revenue metrics rather than direct measures of service delivery or accessibility. Moreover, they often overlooked potential cost-shifting through increased service charges, leaving important questions about nonprofits' tax responses unresolved.

3.2.2 Colleges' Responses to Financial Shock

Research on colleges' responses to endowment shocks provides additional insights. [Brown et al. \(2014\)](#) found that colleges reduce endowment payout and tenured faculty positions following negative investment shocks. [Rosen & Sappington \(2019\)](#) documented that a 10% change in investment returns leads to a 13–14% change in payouts in the same direction. [Bulman \(2022\)](#) showed a 10% endowment increase raises core spending by 2.5% but doesn't affect tuition or aid.

Studies of public colleges’ responses to government funding cuts reveal different patterns. These institutions often respond by increasing tuition and fees (Kane & Orszag, 2003; Mumper & Freeman, 2005; Filippakou et al., 2019; Civera et al., 2021) or reducing spending (Kane & Orszag, 2003; Mumper & Freeman, 2005; Altundemir, 2012). This difference in response patterns — tuition increases following funding cuts but not endowment shocks — may reflect the more permanent nature of funding reductions compared to temporary endowment fluctuations.

4 Data and Sample

4.1 Data

This paper incorporated data from the IPEDS and Form 990. The data period for finance variables spanned 2010 to 2021 and was extended to 2022 for other variables.¹¹ The IPEDS is an annual survey conducted by the U.S. Department of Education’s (ED) National Center for Education Statistics (NCES).¹² All higher education institutions participating in federal student aid programs are required to respond to the survey. The data provides information on colleges’ characteristics, student enrollment (categorized by enrollment status, level of study, and race/ethnicity), and financial information (including subcategories of revenues, expenditures, scholarships, and tuitions).

Form 990 is the tax return filed by tax-exempt organizations.¹³ Nonprofit colleges with gross receipts greater than \$200,000 or total assets greater than \$500,000 are required to file Form 990. Specifically, among approximately 2,000 nonprofit colleges reported in the IPEDS survey, 1,500 (72%) were matched to Form 990 data.¹⁴

¹¹Throughout the paper, the year notation denotes the beginning of the fiscal year or academic year. For most colleges, the fiscal year begins in July and ends in June of the following year. For example, 2017 denotes the fiscal year from July 2017 to June 2018 and the academic year from Fall 2017 to Summer 2018.

¹²The data is available at <https://nces.ed.gov/ipeds/>

¹³The data is available at <https://www.irs.gov/charities-nonprofits/form-990-series-downloads>

¹⁴This paper uses the crosswalk table of Unit ID and Employer Identification Number (EIN) provided by the Urban Institute (see https://educationdata.urban.org/documentation/colleges.html#nccs_990-forms) supplemented by rough matching based on institution names in the IPEDS and Form 990. Some colleges remain unmatched due to name discrepancies between the two datasets. Many colleges that do not file Form 990 are religiously affiliated and exempt from filing the Form 990.

4.2 Variables

The primary variables determining taxation status are student enrollment and total assets. Full-time equivalent (FTE) students are calculated as full-time students plus one-third of part-time students.¹⁵ For assets, I use the “value of endowment assets at the end of the fiscal year” from IPEDS data rather than Form 990, as IPEDS includes assets from both the college and its affiliated organizations. This broader inclusion aligns with IRS requirements for NIIT asset calculations and better matches observed tax status.¹⁶

When defining the tax and treatment status, this paper uses nominal values to measure financial resources. However, to render the estimates of spending or asset changes comparable over time, the monetary variables are adjusted according to the Consumer Price Index (CPI) and denoted as real dollars for the 2010–11 fiscal year.

4.3 Sample

The samples included in this study consist of private nonprofit colleges that participated in the IPEDS survey from 2010 to 2022 and filed Form 990 every year from 2010 to 2021.¹⁷ Following [Fernandez et al. \(2023\)](#), missing values are imputed using data from surrounding years. I exclude colleges that underwent mergers,¹⁸ major expansions, branch closures,¹⁹ or have over 50% remote students.²⁰ These exclusions prevent outcome fluctuations that could distort the analysis.

Colleges were grouped based on enrollment and asset thresholds. Figure 1 shows their distribution by student population (horizontal axis) and per-student endowment assets (vertical axis). The upper-right quadrant indicates colleges meeting both thresholds and subject to tax (Figure 1a), while those near the boundary have incentives for tax avoidance (Figure 1b).

¹⁵This approach matches how the IPEDS defines FTE when calculating student-faculty ratios.

¹⁶While it would be better to use whatever variables the IRS utilizes, the IRS allows colleges to calculate these variables and determine the taxation status themselves. Additionally, the IRS does not require colleges to report student enrollment, only asking them to indicate whether they are subjected to the tax on Form 990.

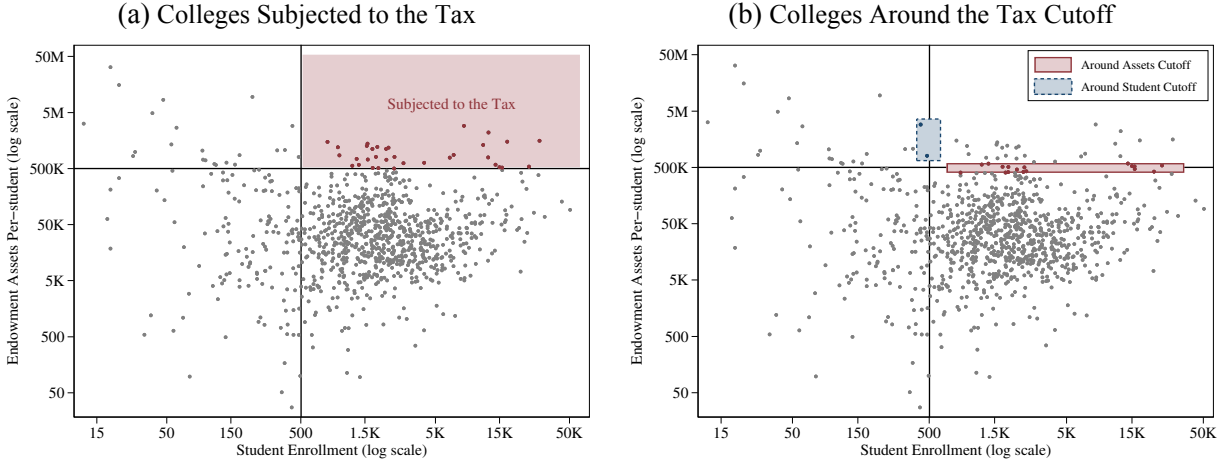

¹⁷I do not require all colleges to have filed Form 990 in the latter years as the timing of organizations doing so vary.

¹⁸Excluded are Thomas Jefferson University and Philadelphia University, which merged in 2017.

¹⁹Exclusions: (1) Mayo Clinic Alix School of Medicine’s Arizona campus expansion (2017), (2) Rensselaer at Hartford’s Groton center closure (2018), (3) Vanderbilt University’s Wond’ry innovation center opening (2015).

²⁰A total of 37 colleges were excluded for this criterion.

Figure 1: Distribution of Samples by Student Enrollment and Endowment Per student

Note: The horizontal axis denotes the total number of students (the sum of full-time and part-time students). The vertical axis denotes the endowment assets per student (full-time equivalent students). Endowment assets are reported in nominal values. The vertical line stands for the student enrollment cutoff. The horizontal line stands for the endowment assets cutoff. Each dot stands for one college. The data is as of the year 2016.

There are only two colleges above the assets cutoff (with more than \$500,000 in assets per student) but close to the enrollment cutoff (with student populations ranging from 400 to 600). Due to the small sample size, this paper opts not to focus on this group.²¹ Conversely, 17 colleges are above the student cutoff (with a student population of more than 500) but are near the asset cutoff (with assets per student between \$400,000 and \$600,000). Nine of these are just above the cutoff (with assets per student within \$500,000 and \$600,000), and another eight are just below the cutoff (with assets per student within \$400,000 and \$500,000). Table 2 summarizes the sample sizes by student population and assets per student in 2016.

Table 1: Sample Size by Student Population and Endowment Asset Per Student

	Endowment Assets Per student			
	Below 400 K	400 to 500 K	500 to 600K	Above 600K
# Students above 500	752	8	9	24
# Students below 500	121	5	2	20

Notes: The number of total students is the sum of full- and part-time students. Endowment assets per student are calculated as endowment asset values divided by full-time equivalent (FTE) students (with one part-time student taken into account as one-third of full-time students). Endowment assets are reported in nominal values.

²¹A SCM has been applied to these two institutions and found no abnormal change in their enrollment.

5 Empirical Strategy

The primary empirical strategy in this paper is a difference-in-differences (DD) design. The DD framework applies to tax avoidance and shifting analysis but with varying sample settings and treatment definitions. Section 5.1 details the empirical setting. Additionally, this paper applies the Synthetic Control Method (SCM) to obtain estimates for each college and uses these results to estimate societal costs and benefits.

A key challenge in the empirical design is that the NIIT applies only to a select number of nonprofit colleges, which differ significantly from institutions unaffected by the policy. This policy's nature makes identifying an ideal comparison group difficult. In the primary analysis, I use all private nonprofit colleges not affected by the policy as the comparison group to retain a larger sample size and retrieve more precise estimates, while acknowledging the potential limitations of this approach.

To address the concerns, I conduct two additional analyses. Firstly, in Appendix B, I restrict the sample to institutions of comparable academic standing and reputation (as defined by Barron's Selectivity Index and U.S. News rankings). While colleges affected by NIIT are often high-ranking and selective, some art colleges and medical schools are wealthy enough to be subject to the tax but may not share the same elite status. This restricted sample provides a more plausible comparison but is not used as the main result to avoid excluding some treated colleges.

Secondly, in Appendix C, I apply a triple-difference (DDD) design, introducing an additional comparison group: wealthy colleges (meeting the asset threshold) with fewer students (not meeting the enrollment cutoff) and thus unaffected by the tax. This approach aims to control for potential trends related to institutional wealth. However, the small sample size of wealthy but small colleges introduces more noise into the estimates.

While each approach has limitations, the consistency of results across these varied methodologies demonstrates the robustness of the findings. By employing multiple strategies and transparently discussing their strengths and weaknesses, this study aims to provide a comprehensive and nuanced analysis of the NIIT's effects on college behavior.

5.1 Difference-in-Differences

The DD model is applied to both tax avoidance and tax-shifting analyses. However, the two analyses use different samples and define treatment and comparison groups differently. Table 2 summarizes the sample construction and treatment status definitions for both analyses. Sections 5.1.1 and 5.1.2 detail the empirical setup.

Table 2: Sample Construction of DD Setting

	Sample	Treatment Group	Comparison Group
Tax Avoidance			
Sample	Private non-profit colleges with more than 500 students and with less than \$600,000 assets per student in 2016.	Colleges around the assets-related tax threshold — with assets per student between \$400,000 and \$600,000 in 2016.	Colleges far below the assets-related tax threshold — with assets per student less than \$400,000 in 2016.
# Colleges	769	Just Below Cutoff: 8 Just Above Cutoff: 9	752
Tax Shifting			
Sample	Private non-profit colleges with more than 500 students in 2016 and <i>excludes</i> colleges around the tax threshold — with assets per student between \$400,000 and \$600,000 in 2016.	Colleges above the assets-related tax threshold — with assets per student greater than \$600,000 in 2016.	Colleges below the assets-related tax threshold — with assets per student less than \$400,000 in 2016.
# Colleges	776	24	752

Notes: The number of total students is the sum of full- and part-time students. Endowment assets per student are calculated as endowment asset values divided by full-time equivalent (FTE) students (with one part-time student taken into account as one-third of full-time students). Endowment assets are reported in nominal values.

5.1.1 Tax Avoidance

In analyzing tax avoidance, the sample is limited to colleges that meet the tax threshold for student enrollment (with total student above 500 in 2016). I also exclude colleges that are far above the tax threshold related to assets per student (with assets per student above \$600,000 in 2016), as these institutions are certain to be taxed and have no practical means for tax avoidance.

The DD setup compares colleges that are *around* (treatment group) and *far below* (comparison group) the assets-per-student threshold, with distance from the cutoff defined using pre-policy values (as of 2016). This design assumes that only colleges near the threshold have incentives to manipulate their enrollment and asset values for tax exemption.

Notably, the treatment group includes colleges both just above and below the tax threshold. Table A3 in Appendix A shows colleges' proximity to assets-per-student thresholds. Colleges just above the cutoff need only minor adjustments (0.05–15% asset decrease or 0.05–17% student increase) to qualify for exemption, with some requiring fewer than 50 additional students. Colleges just below the cutoff also face incentives, as the threshold remains static despite inflation and endowment growth. These institutions would meet the threshold with 7–24% endowment growth, but many average 3–6% annual growth, potentially becoming subject to the tax within 3 to 4 years. Both groups thus have strong incentives to adjust promptly after policy implementation.

In contrast, colleges far below the cutoff (the comparison group) face no immediate tax liability and thus have no motivation for tax avoidance. The analysis compares outcome changes across time between colleges with and without avoidance incentives. The estimation equation is:

$$Y_{it} = \beta_1 Cutoff_i \times Post_t + \theta_i + X_i \times \delta_t + \varepsilon_{it} \quad (1)$$

Where Y_{it} is the outcome of interest for college i in year t . $Cutoff_i$ is a dummy variable indicating whether the college is near the cutoff (i.e., having endowment assets per student between \$400,000 to \$600,000 in 2016). $Post_t$ is a dummy variable indicating whether the policy is effective, with 0.5 for 2017 and 1 after 2018, as the 2017–18 fiscal year was partially affected. In the robustness check, I test different specifications where I treat the year 2017 as 0% to 100% treated or drop the 2017 observations (see Figures A2 and A3). The estimates remain consistent across specifications. θ_i is the college fixed effect. δ_t is the year fixed effect. The equation further includes the time-invariant college characteristics-by-year fixed effect ($X_i \times \delta_t$). This paper includes the Carnegie categorization interacting with the time variable to establish comparisons among institutions of the same type. ε_{it} is the error term. The key parameter of interest is β_1 , indicating the responses of colleges near the cutoff following the policy's implementation.

The identification assumption within this setting is that the colleges near the cutoff should have followed the same outcome trend as those far from the cutoff in the absence of the policy. This paper evaluates this assumption by examining the pre-policy parallel trend using an event-study design. Additionally, robustness checks in the Appendix using alternative comparison groups and a DDD design further validate the main findings by addressing potential concerns about differential trends between treated and control institutions.

5.1.2 Tax Shifting

Within the tax shifting analysis, attention is directed toward colleges meeting the tax threshold on student enrollment (with total student above 500 in 2016), and compares those *meeting* and *not meeting* the assets per student threshold. Those meeting the threshold would be subjected to the NIIT, while those not meeting it would be exempted. The treatment status is defined using pre-policy values (as of 2016). Additionally, colleges near the cutoff (i.e., with endowment assets per student in 2016 between \$400,000 to \$600,000) are excluded, as their response might be confounded by tax avoidance behavior. Therefore, the analysis compares the change in outcomes over time between colleges subjected to and not subjected to taxation. Specifically, the following equation is estimated:

$$Y_{it} = \beta_1 Treat_i \times Post_t + \theta_i + X_i \times \delta_t + \varepsilon_{it} \quad (2)$$

$Treat_i$ is a dummy variable indicating that the colleges met the tax threshold (i.e., had endowment assets per student greater than \$500,000) in 2016. The definitions of Y_{it} , $Post_t$, θ_i , δ_t , X_i , and ε_{it} are the same as in equation (1).

The identification assumption is that colleges subject to the tax should have followed the same outcome trend as those exempt from the tax in the absence of the policy, at least conditionally based on the fixed effect. The event study version of equation (2) ensures that the treatment and comparison groups follow a similar trend prior to the policy. In the robustness check, the empirical setting and sample construction were further adjusted to examine the sensitivity of the analysis. The results are robust across this alternative specification.

The key parameter β_1 in equation (2) captures the relative change in outcomes for tax-subjected colleges versus the control group after policy implementation. While treatment status is defined using pre-policy variables and typically represents intent to treat (ITT), the primary analysis excludes colleges near the cutoff, making status changes unlikely. Thus, the estimate approximates the average treatment effect on the treated (ATT). Results remain robust when using the full sample.

5.2 Synthetic Control Method

DD models are helpful in constructing the average treatment effect but would be limited in understanding the heterogeneous response. Since each college is distinct in terms of its proximity to the threshold and the size of the expected tax payment (see Table A2 and A3 in Appendix A), understanding the treatment effect on individual colleges is crucial.

This paper utilizes the SCM to examine the treatment effect on each individual college. SCM constructs the counterfactual of a single observation by using a weighted combination of non-treated observations (the donor pool). The weights are then determined by minimizing the difference in pre-intervention observed characteristics (Abadie et al., 2010).

This paper utilizes the demeaned pre-treatment outcome variables to compute the SCM weights. Specifically, each pre-treatment outcome variable subtracts the mean of the institution during the pre-intervention period. This practice, similar to the inclusion of the institution fixed effect in the DD model, provides the benefit of improving the pre-treatment fit (Doudchenko & Imbens, 2016).

In the tax avoidance analysis, the treatment group is comprised of colleges near the asset cutoff, while the donor pool consists of those far from the asset cutoff. In the tax shifting analysis, the treatment group comprises colleges subjected to the tax, while the donor pool includes colleges that meet the student threshold but not the asset threshold. Colleges near the cutoff are excluded. The estimation is performed separately for each college using the following formula:

$$\widehat{\beta}_{it} = (Y_{it} - \bar{Y}_i) - \sum_{j=1}^M w_j^* (Y_{jt} - \bar{Y}_j) \quad (3)$$

Where the estimated treatment effect ($\widehat{\beta}_{it}$) is defined as the difference between the observed demeaned outcome of the treated college ($Y_{it} - \bar{Y}_i$) and the synthetic control ($\sum_{j=1}^M w_j^* (Y_{jt} - \bar{Y}_j)$), constructed as a weighted average of the colleges in the donor pool. w_j^* is a vector of weights that minimizes the difference in the pre-treatment outcomes. j is each of the control units in the donor pool, and M is the total number of units in the donor pool. To provide inference statistics, this paper employs a permutation test. The permutation method details are discussed in Appendix D.

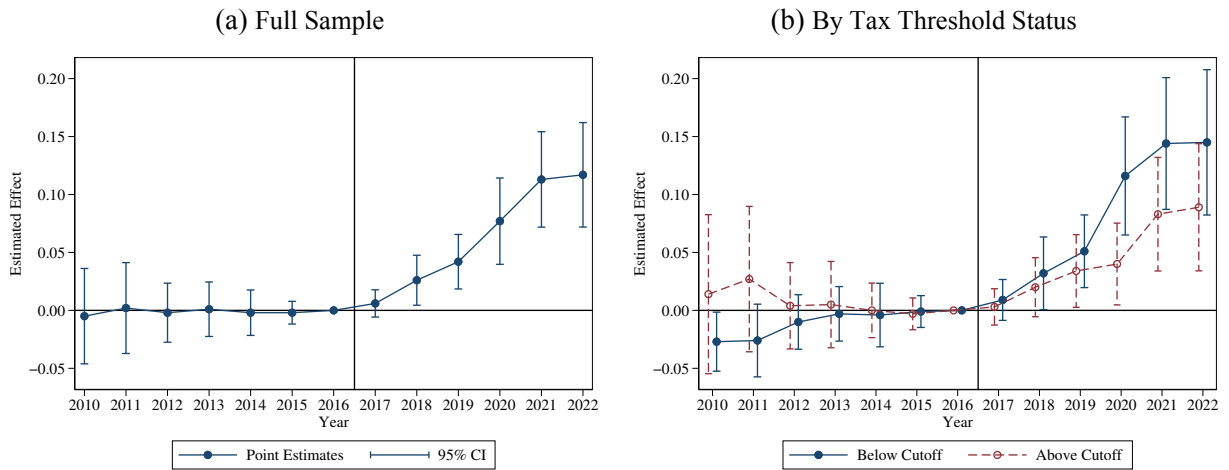

6 Empirical Results

6.1 Tax Avoidance

6.1.1 Average Response

The results reveal that colleges near the assets-per-student threshold tend to manipulate their student enrollment rather than asset size. Figure 2a presents the event study estimates on enrollment. The figure confirms the DD assumption by showing common pre-policy trends in enrollment for colleges near and far from the tax cutoff. After the policy takes effect, colleges near the tax threshold begin to increase their student enrollment, with the effect magnitude growing over time.

Figure 2: Event Study: Student Enrollment-Related Tax Avoidance Behavior

Note: The coefficients are estimated using the event study version of equation (1). The error bars denote the 95% confidence interval. The outcome variables are the log number of FTE student enrollment.

Table 3 provides the pooled estimates of the post-policy average effect, showing a 7.6% increase in FTE enrollment ($p < 0.01$, see Panel A, Column (1)) for colleges with avoidance incentives. This effect represents approximately 500 additional students per institution. The enrollment increase is predominantly driven by full-time students (up 7.7%) and undergraduate students (up 7.1%).

Table 3: Student Enrollment-related Tax Avoidance Behavior

	(1)	(2)	(3)	(4)	(5)
	Log FTE	By Enrollment Status		By Student Level

Observations	9,893	9,893	9,893	9,893	9,893
Baseline Mean (Thousand)	8.103	7.798	0.915	4.246	3.857

Note: The coefficients are estimated using equation (1). Standard errors clustered at the institution level in parentheses. Panel B restricted the treatment group to colleges with assets per student between \$400,000 and \$500,000 in 2016. Panel C restricted the treatment group to colleges with assets per student of between \$500,000 and \$600,000 in 2016. For both panels, the comparison group consists of colleges with assets per student less than \$400,000 in 2016. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

Figure 2b explores heterogeneous responses. Colleges just below the cutoff show more pronounced responses, with effect magnitudes approximately double those of colleges just above the cutoff. However, both groups demonstrate positive and significant effects. Panels B and C of Table 3 also report colleges below the tax threshold with larger enrollment expansions than those above, suggesting that institutions manipulate student enrollment to avoid future tax exposure.

Figure 3 examines responses in endowment assets. The event study estimates again demonstrate parallel pre-policy trends in outcomes. The dynamic treatment effect estimates show that colleges around the cutoff do not reduce their assets; instead, there is an upward trend in endowment assets after 2020, likely due to strong investment market performance following the COVID-19 pandemic.

Figure 3: Event Study: Endowment-Related Tax Avoidance Behavior

Note: The coefficients are estimated using the event study version of equation (1). The error bars denote the 95% confidence interval. The outcome variables are the log endowment assets and log endowment assets per student.

Table 4 presents average post-policy changes. Colleges near the tax threshold show a statistically insignificant 4.3% increase in total endowment ($p > 0.1$; Panel A, Column (1)), primarily driven by growth in capital and investment assets. Increased enrollment and stable endowments led to a non-significant 2.5% decrease in endowment assets per student (Panel A, Column (2)). Colleges below the threshold show a significant 8.4% reduction in endowment assets per student, primarily due to increased student population (Panel B, Column (2)). This 8% reduction effectively offsets their average asset value growth, potentially preserving their tax-exempt status.

6.1.2 Robustness Check

A key concern is that tax-affected colleges, typically wealthy and prestigious, may respond differently to macro conditions than unaffected institutions. I address this by creating two restricted samples: one including only colleges with high Barron's Selectivity Index ratings (most to very competitive), and another limited to US News top 100 institutions (National Universities or Liberal Arts Colleges). Table 5 shows key findings, with complete results in Appendix B. The estimated effect remains consistent. Colleges around the cutoff significantly increase their enrollment by 7.6% (selective colleges subsample; see column (1) of Table 5) or 5.7% (top-ranking college subsample; see column (3) of Table 5), very close to the 7.5% estimate of the main result.

I also conducted a DDD design comparing colleges with similar wealth but smaller student size. Appendix C provides methodological details and comprehensive results, while Table 5 illustrates the key insight. The results align with the main findings about increased enrollment, though the estimates are noisier. Nevertheless, the event study result (see Figure C2) suggests that the positive trend in student enrollment is likely to be real.

Table 5: Tax Avoidance Behavior: Robustness Checks

	(1)	(2)	(3)	(4)	(5)	(6)
	Barron's Index \geq Very Competitive		US News' Ranking Top 100		DDD

Standard errors clustered at the institution level in parentheses. Columns (1) to (3) restrict to those with Barron's Selectivity Index as most competitive, highly competitive, or very competitive. Columns (4) to (6) restrict to those with US News Ranking among the top 100 in 2016. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

6.1.3 Individual Institution Response

Figure 4 shows the evaluation of effects on individual institutions using SCM. All colleges near the cutoff increased enrollment after the policy (see Figure 4e). The University of Chicago had the largest response, with an enrollment increase of 18%,²² followed by Colby College (13% increase),²³ Washington University in St Louis (11%),²⁴ and Duke University (11%).²⁵ The average estimate among all colleges is 0.085 ($p = 0.008$), which aligns with the DD model result.

Regarding the response related to assets per student, half (9 of 17) of the colleges show a negative change in this variable, ranging from a negative 14% to a positive 16% (see Figure 4f). The institutions with the most substantial negative responses are Wabash College (-13%), the University of Chicago (-12%), and Northwestern University (-9%).

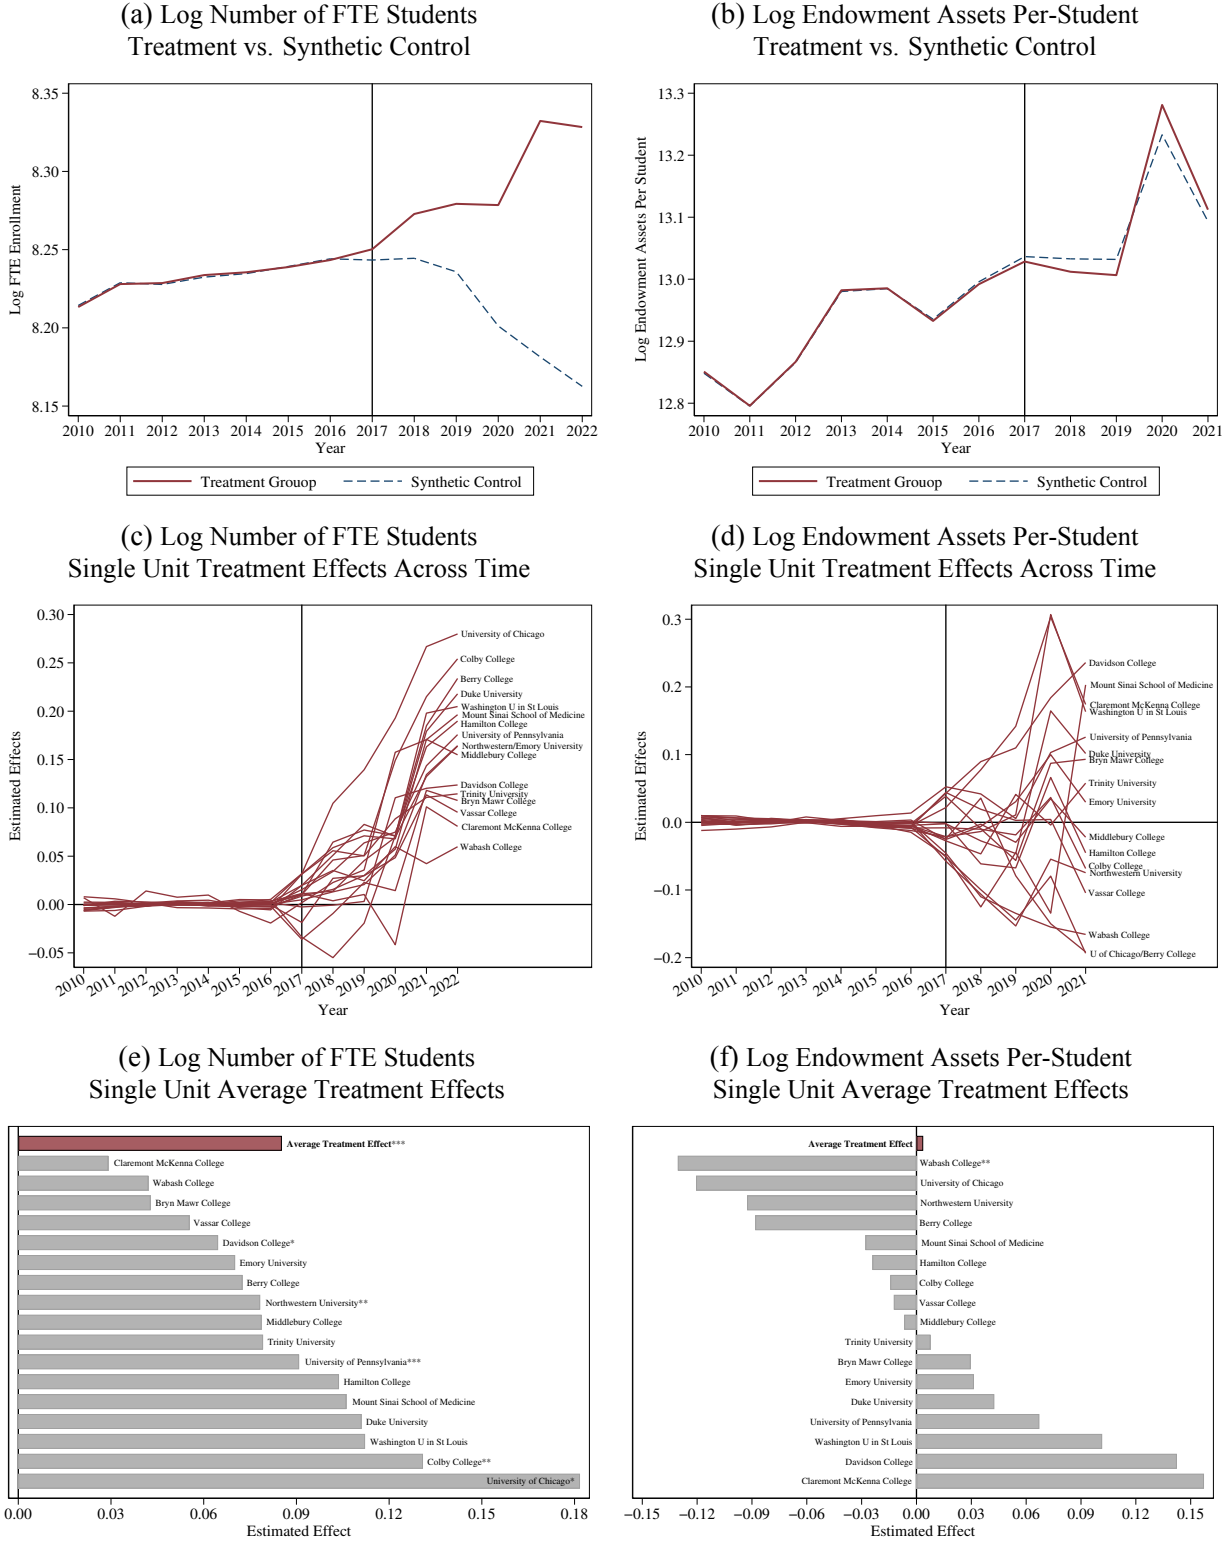

²²Public records suggest that the increase in enrollment at UChicago is due to an intentionally adopted strategy (IVY COACH, 2018). In 2018, the Dean of College at UChicago announced the plan to expand the undergraduate student body (Yee, 2018). Their student body showed an increase from 6,300 in 2017 to 7,000 in 2020.

²³Colby College sets up a five-year strategic plan. Their 2017–2022 plan had a specific goal to “employ strategies to expand revenue through increased enrollment.” However, such goals were absent in their 2012–2017 plan. Instead, at that time, their plan was to manage enrollment based on their “current capacity.” (See <https://www.colbycc.edu/about/strategic-plan-mission.html>.) Their student body has increased from 1,800 in 2017 to 2,200 in 2022.

²⁴WashU established a new office, the Academy for Diversity, Equity, and Inclusion, in 2018. While the primary goal of the office is equity, the university has proposed a series of strategies, including forging partnerships with community-based organizations to enhance college access for disadvantaged students and launching recruitment programs in rural areas to reach high school graduates (Riley, 2019; Keaggy, 2022; Blake, 2024).

²⁵Duke's enrollment increase was more driven by graduate students. In 2017–2018, Duke established a new center, The University Center of Exemplary Mentoring (UCEM), and initiated programs to “expand Duke's capacity to attract, retain, and graduate STEM doctoral students” (Saff, 2018; Vashisth, 2018). The program led to a surge in graduate students, with the total number of FTE graduate students increasing from 9,000 in 2017 to 11,000 in 2022.

Figure 4: Synthetic Control Method: Tax Avoidance Behavior

Note: The synthetic controls are estimated using SCM. The treatment effects are estimated using equation (3). The error bars denote the 95% confidence interval. The samples are private nonprofit colleges that reported in IPEDS and filed Form 990 every year from 2010 to 2022, with a student population above 500 in 2016. FTE (full-time equivalent) is calculated as the sum of full-time and one-third of part-time students.

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

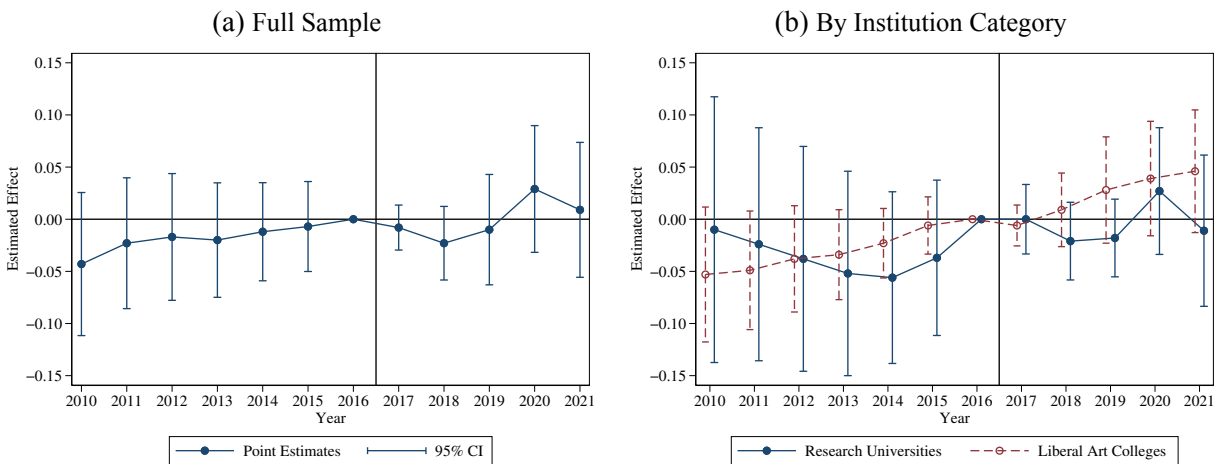

Using SCM-derived counterfactuals, I identified colleges that avoided tax liability through manipulation. The manipulation allows two colleges — University of Chicago and Berry College — that could have been taxed in 2018 to be exempt. In 2019 and 2020, Trinity University and Northwestern University joined the group that “successfully avoided the tax.” In 2021, Wabash College could have met the threshold but has been exempted due to manipulation. Vassar College and Colby College were subjected to the tax in 2021 and should have continued in 2022, but due to increases in enrollment, they were exempted. Overall, tax avoidance behavior has allowed seven colleges to be (temporarily) exempted or delay the timing they would be subjected to taxation. The estimated tax loss due to avoidance is \$31 million (in 2010 real dollars) over five years.

6.2 Tax Shifting

6.2.1 Average Response

This study finds no evidence of reduced spending due to taxation. The event study evidence in Figure 5a shows good common trends in total expenditure between the treatment and comparison groups prior to the policy. There is no substantial change in total spending after the policy enactment.

Figure 5: Event Study: Expenditure-Related Tax Shifting Behavior

Note: The coefficients are estimated using the event study version of equation (2). The error bars denote the 95% confidence interval.

Table 6 provides the average effect, suggesting that taxation leads to an insignificant 2% increase in total spending (see Panel A, Column (1)). Figure 5b and Table 6 Panels B and C separate samples into research universities and liberal arts colleges. Both show no significant changes.

Table 6: Expenditure-related Tax Shifting Behavior

	(1)	(2)	(3)	(4)	(5)	(6)	(7)

Note: The coefficients are estimated using equation (2). Standard errors clustered at the institution level in parentheses. Outcomes are log expenditures by category: (1) total expenditure, (2) instruction and academic support, (3) research and independent operations, (4) public service, (5) institutional support (operations, administration, management), (6) auxiliary facilities, hospitals, and student services, and (7) net institutional grant aid (scholarships and fellowships). All dollars are adjusted by CPI and denoted in 2010 real dollars. Panel B restricted the sample to colleges categorized as doctoral or master institutions in the Carnegie categorization. Panel C restricted the sample to colleges not categorized as doctoral or master institutions in the Carnegie categorization.

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

In contrast, colleges respond to taxation by shifting costs to students. Figure 6 presents the event-study evidence on student enrollment and tuition setting. The pattern shows an increase in student enrollment at liberal arts colleges but not research universities (see Figure 6a). However, both groups show an increase in tuition. Research universities increased graduate tuition by 4% in 2019 and increased this to approximately 7% in 2022 (see Figure 6c). Liberal arts colleges increased undergraduate tuition by 2% in 2018 and by 6% in 2022 (see Figure 6b).

Table 7 presents the average policy effect, finding that taxed colleges increased their listed tuition and charges for room and board after the policy went into effect. Substantial heterogeneous responses exist across institution types. While liberal arts colleges increased their undergraduate tuition by 3.4% (Panel C, Column (2)), research universities opted to increase the graduate tuition by 6.8% (Panel B, Column (3)). Liberal arts colleges also increased their charges for room and board by 5% (Column (4)).

Figure 6: Event Study: Enrollment and Charge-Related Tax Shifting Behavior

Note: The coefficients are estimated using the event study version of equation (2). The error bars denote the 95% confidence interval.

Observations	6,019	6,019	6,019	6,019	5,556	5,556	5,556	5,556
Baseline Mean (Thousand)	1.795	40.210	21.015	11.800	48,815	26.808	19,028	9.785

Note: The coefficients are estimated using equation (2). Standard errors clustered at the institution level in parentheses. Panel B restricted the sample to colleges categorized as doctoral or master institutions in the Carnegie categorization. Panel C restricted the sample to colleges not categorized as doctoral or master institutions in the Carnegie categorization. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

The results reveal increased enrollment, but only among liberal arts colleges, which experienced a significant 6% increase in student enrollment ($p < 0.01$, see Panel C, Column (1)). Increasing enrollment might be a strategy to boost revenue, as evidenced by a 21% increase in total tuition revenue (see Table 7 Panel C, Column (5)) despite the listed tuition only increasing by 3%.

6.2.2 Robustness Check

A concern is that colleges in the comparison group differ greatly from those in the treatment group, potentially failing to provide a valid counterfactual. Appendix B addresses this issue by using colleges with equivalent selectivity and reputation as the comparison group. Table 8 provides key estimates, while the Appendix presents the full results. The results mirror the main findings. Taxed colleges maintain spending but increase listed tuition by 2–3 %, close to the main estimate.

Table 8: Tax Shifting Behavior: Robustness Checks

	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)
	Barron's Index \geq Very Competitive			US News' Ranking Top 100			DDD		
	Total Exp.	Listed Tuition	Tuition Rev.	Total Exp.	Listed Tuition	Tuition Rev.	Total Exp.	Listed Tuition	Tuition Rev.
<i>Wealthy \times Post</i>	0.005 (0.036)	0.027* (0.014)	0.109** (0.047)	-0.055 (0.050)	0.018* (0.010)	0.042 (0.050)			
<i>Large \times Wealthy \times Post</i>							0.002 (0.043)	0.100*** (0.033)	0.214 (0.212)
Observations	3,324	3,601	3,324	1,380	1,495	1,380	11,004	11,004	11,004

Note: The coefficients are estimated using equation (2). Standard errors clustered at the institution level in parentheses. The outcomes are log total expenditure (Columns (1), (4), and (7)), log listed undergrad tuition (Columns (2), (5), and (8)), and log total tuition revenue (Columns (3), (6), and (9)). Samples are private non-profit colleges that reported in IPEDS and filed Form 990 yearly from 2010 to 2022, with a student population above 500 in 2016. Columns (1) to (3) restrict to those with Barron's Selectivity Index as most competitive, highly competitive, or very competitive. Columns (4) to (6) restrict to those with US News Ranking among the top 100 in 2016. The observation period is from 2010 to 2022 for listed tuition and 2010 to 2021 in the remaining columns. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

I employed a DDD design to further address this concern. Appendix C presents the details, while Table 8 demonstrates the key estimates. Finding shows a null response in spending and a positive increase in tuition. The point estimate on tuition increase is larger than the main results, potentially because small, wealthy colleges were able to maintain lower tuition during the pandemic while large, wealthy colleges (the taxed colleges) did not. Despite some variation in magnitude, the key insights remain consistent across these robustness checks.

6.2.3 Individual Institution Response

Figure 7 examines the individual institutional responses using the SCM. The estimated responses of the effect on total expenditure range from a decrease of 16% to an increase of 12% (see Figure 7e). However, most estimates are not significant. The average treatment effect retrieved from pooled SCM is 0.00004 ($p = 0.135$), which is essentially null.

In terms of tuition revenue, 20 out of 24 colleges saw increases in total tuition revenue.²⁶ The magnitudes range from an increase of 27% to a decrease of 4% (see Figure 7f). The average treatment effect retrieved from pooled SCM is 0.07 ($p = 0.01$), close to the DD model's estimate.

6.3 Impact on Student Composition

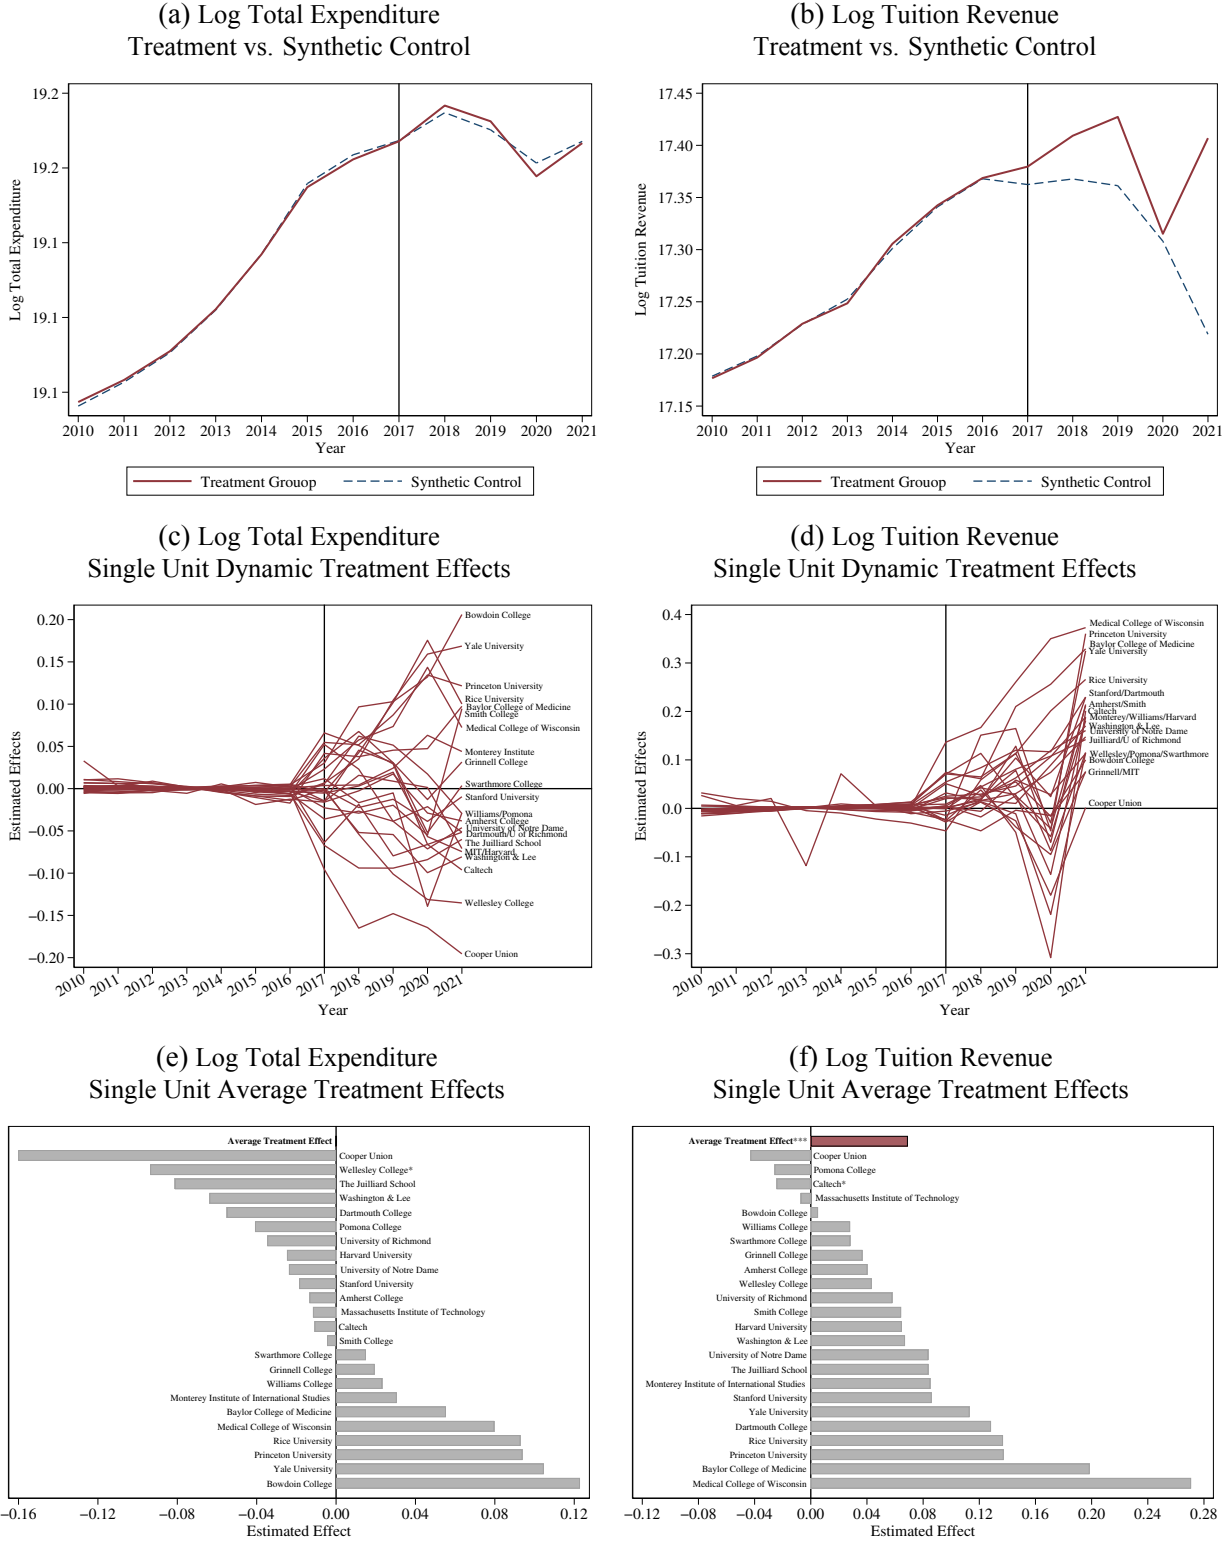

Earlier results show that colleges increase student enrollment to qualify for tax exemption (Section 6.1) and raise tuition to shift tax burdens (Section 6.2). This section examines how these responses affect educational opportunities by analyzing changes in student racial/ethnic composition and financial aid status.

Table 9 presents enrollment changes by race/ethnicity. Tax avoidance-driven enrollment increases appear to benefit all student groups. Panel A shows enrollment increases across all racial categories, with White students showing a significant 9.1% increase ($p < 0.01$; Column (1)). While Black, Hispanic, and Asian student enrollment also increases, these changes are not statistically significant. Other minorities show a substantial 20% increase ($p < 0.01$; Column (5)), primarily driven by students identifying as two or more races or ethnicities.

However, increased education costs from tax shifting disproportionately affect historically underrepresented groups. Tax-paying colleges experience a significant 13% decrease in Hispanic enrollment ($p < 0.01$; Panel B, Column (3)). Conversely, international student (nonresident alien) enrollment increases by 10% ($p < 0.1$; Panel B, Column (6)), suggesting colleges may be recruiting students who can pay higher tuition rates.

²⁶This analysis takes total tuition revenue as a summarized index of change in the listed tuition prices and total enrollments. When separately examining tuition changes, 22 colleges increased their undergraduate tuition, and 21 colleges increased their graduate tuition.

Figure 7: Synthetic Control Method: Tax Shifting Behavior

Note: The synthetic controls are estimated using SCM. The treatment effects are estimated using equation (3). The error bars denote the 95% confidence interval. The samples are private nonprofit colleges that reported in IPEDS and filed Form 990 every year from 2010 to 2022 and exclude colleges with endowment assets per student between \$400,000 and 600,000 in 2016.

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

Panel D: Tax Shifting, Liberal Arts Colleges						
<i>Treat × Post</i>	0.052 (0.036)	−0.011 (0.044)	−0.129** (0.056)	0.063 (0.053)	−0.088 (0.064)	0.162** (0.077)
Observations	6,019	6,019	6,019	6,019	6,019	6,019
Baseline Mean (Thousand)	2.739	0.336	0.516	0.840	0.262	1.159

Note: The coefficients in Panel A are estimated using equation (1). The coefficients in Panel B to D are estimated using equation (2). Standard errors clustered at the institution level in parentheses. The outcomes are log full-time equivalent (FTE) students by race/ethnicity. Other minorities include Native Hawaiian and Pacific Islander (NHPI), American Indians and Alaska Natives (AIAN), and two or more races. NRA stands for non-resident alien. Panel C restricted the sample to colleges categorized as doctoral or master institutions in the Carnegie categorization. Panel D restricted the sample to colleges not categorized as doctoral or master institutions in the Carnegie categorization. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

While liberal arts colleges increase overall enrollment, this growth is largely driven by international students (16% increase, $p < 0.05$, Table 9 Panel D, Column (6)). White and Asian enrollment shows non-significant increases (5% and 6%, respectively), while Hispanic enrollment decreases significantly by 13% ($p < 0.05$, Column (3)). These patterns suggest that tax-shifting-driven enrollment increases primarily benefit international but hurt domestic underrepresented groups.

Table 10 examines enrollment changes based on financial aid status among first-time degree-seeking undergraduate students (the only group with mandatory reporting). Tax avoidance-driven enrollment increases particularly benefit Pell Grant recipients — typically low-income students — showing a 20% increase ($p < 0.01$; Panel A, Column (3)). The absence of significant changes in institutional aid recipients (Panel A, Column (5)) suggests that while colleges expand enrollment opportunities, they do not support additional students with institutional financial aid.

Note: The coefficients in Panel A are estimated using equation (1). The coefficients in Panel B to D are estimated using equation (2). Standard errors clustered at the institution level in parentheses. The outcomes are the log number of full-time, first-time degree/certificate-seeking undergraduate students based on different financial aid statuses. Panels B to D exclude colleges with endowment assets per student between \$400,000 and 600,000 in 2016 (i.e., only include the donut sample). Panel C restricted the sample to colleges categorized as doctoral or master institutions in the Carnegie categorization. Panel D restricted the sample to colleges not categorized as doctoral or master institutions in the Carnegie categorization.

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

Conversely, tax-shifting most severely affect students relying on Federal Student Loans, who typically from middle-low-income families ineligible for Pell Grants but unable to self-finance their education. These students face a substantial 28.5% enrollment decrease ($p < 0.01$; Panel B, Column (4)). While Pell Grant recipients show a 15% enrollment increase ($p < 0.01$; Panel B, Column (3)), this implies that the federal government may bear the burden of increased costs. The unchanged enrollment among institutional aid recipients (Panel B, Column (5)) indicates that colleges do not expand aid programs despite raising costs.

The enrollment increase in tax-paying liberal arts colleges appears primarily driven by students receiving no financial aid (see Panel D, Column (1)), consistent with the earlier finding of increased international student enrollment (Table 9).

6.4 Monetizing Policy Outcomes

6.4.1 Comparing Revenue Loss and Opportunities Generated

Tax avoidance behavior, while leading to government revenue loss, prompts selective colleges to increase enrollment. Studies suggest positive effects of attending selective colleges on academic and labor market outcomes (Melguizo, 2008; Kapur et al., 2016; Witteveen & Attewell, 2017; S. D. Zimmerman, 2019; Ge et al., 2022), implying potential benefits from expanded access.

To evaluate the benefits of enrollment expansion, I calculate the additional return of college degrees from these colleges compared to degrees from colleges that are one level lower in selectivity. The methodology is detailed in Appendix E. Using various assumptions, the total estimated net benefit (including individual and societal benefits) ranges from \$350 million to \$1,300 million.

Taking the lower bound of these estimates, the benefit generated from enrollment (\$350 million) is over ten times the revenue loss (\$31 million throughout the five-year period) due to tax avoidance. This underscores the potential social value created through enrollment expansion in response to tax incentives, emphasizing the broader positive outcomes beyond fiscal considerations.

However, this interpretation has limitations. The benefit calculation includes all 17 colleges engaged in avoidance behaviors, while tax loss considers only 5 successful cases. Therefore, the comparison refers to an overall policy effect and does not imply that granting a \$1 tax exemption would lead to a \$10 social benefit. Additionally, this short-term estimate does not account for potential long-term changes in college motivation for manipulation as endowments grow.

6.4.2 Comparing Taxes Paid and Amount Shifted to Students

The evidence in the prior sections reveals that taxed colleges increase tuition and charges, raising the question of how taxes paid compared with the burden shifted to students. A comprehensive estimate using SCM for individual institutions over 5 years shows \$1,186 million shifted through tuition and \$249 million through auxiliary charges (2010 real dollars).²⁷ In contrast, the estimated

²⁷This estimate is based only on the treatment group in the analysis sample, thus excluding colleges near the tax threshold and those that initially were not, but might later be, subjected to the tax.

tax revenue from the NIIT for the same analysis sample is approximately \$1.621 billion (in 2010 real dollars) throughout the 5-year sample period. Combining these calculations, colleges shifted 88% of their tax burden to students. Thus, for each \$1 of taxes paid for the NIIT, colleges increase students' attendance cost by \$0.88.

7 Conclusion

Nonprofits have long benefited from generous tax exemptions, representing a form of invisible government support through tax spending. However, scholars have raised concerns regarding the justification for this tax exemption, questioning whether nonprofits utilize the tax benefits to enhance their services ([D. Zimmerman, 1991](#); [Cowan, 2007](#); [Nichols & Santos, 2016](#); [Herring et al., 2018](#); [Propheter, 2019a](#)). The consideration of whether the government should tax nonprofits is dependent on how nonprofits respond to taxation. They might engage in tax avoidance behavior by manipulating their finances or services or shift the tax burden onto their service population or the public. Prior studies examining for-profit organizations have revealed that tax avoidance and shifting behaviors can result in inefficiency or inequity ([Nerudová & Dobranschi, 2016](#); [Farrell, 2017](#); [Felix, 2007](#); [Bird & Davis-Nozemack, 2018](#); [G. Taylor et al., 2019](#)). However, few studies have examined how nonprofits' responses to taxation translate into societal benefits or losses, and whether the consequences outweigh the revenues from taxation.

This paper explores how nonprofits respond to government taxation by examining nonprofit colleges' reactions to the NIIT introduced by the TCJA. This policy represents the government's first attempt at regulating public charities' endowments and taxing their investment income. The context provides a unique opportunity to evaluate nonprofits' responses to taxation and whether these responses might reduce the provision of public goods and diminish overall societal benefits.

This paper identifies three key findings. Firstly, it reveals that nonprofit colleges engage in tax avoidance behavior but in a manner that benefits society. The NIIT targets colleges with more than 500 students and over \$500,000 in endowment assets per student, allowing colleges to manipulate

their student enrollment or endowment assets to maintain their tax exemption. The findings also suggest that colleges near the threshold responded by increasing enrollment rather than reducing endowment assets, aligning with theoretical expectations that nonprofits maximize service output (Brooks, 2005; Chang & Jacobson, 2011). This pattern is evident at the aggregate level and is common among colleges near the threshold. This behavioral pattern offers the government an opportunity to design tax policies that guide nonprofits in socially beneficial ways.

Secondly, this paper examines tax-shifting behavior, revealing that taxed colleges increase tuition and charge for on-campus facilities, passing the tax burden onto students. However, they do not reduce financial aid or expenditures, despite claims in public statements and lobbying. This aligns with previous studies indicating that taxes on nonprofits might not impact service levels (Grimm Jr, 1999; Fei et al., 2016; Herring et al., 2018). Colleges' choice to increase tuition instead of reducing services aligns with studies finding that colleges facing financial fluctuations maintain or improve their quality (Bulman, 2022). These findings support theoretical perspectives that nonprofits prioritize social welfare and their missions when facing tax burdens.

The response pattern also has implications for public goods provision. In the specific context evaluated in this paper, colleges facing taxes choose not to reduce their service quantity (i.e., reduce student enrollment) or quality (i.e., cut spending), but increase costs for their service population to access services (i.e., increase tuition and charges). While this behavioral response does not alter the overall service level, it may change the distribution of service access. Specifically, analysis suggests that tuition increases redistribute enrollment from historically underserved groups (particularly Hispanic students) to international students who may possess more financial resources. Additionally, the increased attendance cost also hinder education opportunities for student from middle-low income families who rely of student loan.

In terms of the magnitude of the response, the estimation from SCM suggests that for each \$1 paid to the government, colleges increase the attendance cost to students by \$0.88. This response magnitude concurs with the ranges seen in prior literature on the tax-shifting behaviors of firms. Specifically, past studies of various goods found that for each \$1 increase in tax, retail

prices increased by \$0.6 to \$1.4 (Marion & Muehlegger, 2011; Espinosa & Evans, 2013; Bonnet & Réquillart, 2013).

However, this response magnitude is greater than those observed in previous studies on colleges' responses to endowment shocks. For example, Bulman (2022) found a 10% endowment shock driven by the investment market leads to a 2.5% change in core spending, which is much lower than the estimate in the present study.²⁸ The reason that these colleges' response magnitudes are more aligned with firms' tax-shifting behaviors rather than how colleges respond to their endowment returns could be due to the structure of the income shock. Changes in spending or revenue require budget adjustments that are difficult to significantly alter in a short period. While the NIIT is based on endowment returns, colleges only have to pay the bill after the return is realized and not until the following year when the tax return is due. Hence, it is easier for colleges to adjust budgets in response to taxation. Additionally, tax payments might be viewed as an institutional cost, while investment shocks may be considered temporary, with losses in one year potentially compensated in another. Therefore, institutions might respond more to taxation than to investment shocks.

Finally, a detailed analysis of costs and benefits finds that tax avoidance behaviors led to a \$31 million loss in tax revenue over a five-year period but created an additional 9,600 enrollment opportunities, translating to over \$350 million in personal or social benefits. In contrast, taxation earned the government \$1,621 million in revenue over the same period but also imposed higher attendance costs for students, totaling \$1,435 million (88% of the total tax payment). Overall, for this specific policy, the total benefits (sum of government revenue and the implied benefits due to enrollment expansion) may exceed the burden borne by society (the increased costs borne by students). However, despite the overall increase in societal benefits, concerns about equity (redistribution of educational opportunity) should not be ignored. Whether the policy is ultimately beneficial depends on whether the government can use the generated revenue to compensate the groups harmed by the policy.

Based on these findings, this paper offers several policy recommendations regarding the NIIT

²⁸Using the sample construction as used in Bulman (2022), this figure can be transformed into a 25% revenue shock and a corresponding 2.4% total spending cut.

on colleges and nonprofit taxation in general. Firstly, while the NIIT on colleges has some negative consequences, the worst-case scenario (cutting spending and financial aid) did not occur. Additionally, the benefits generated from the policy exceed the negative costs, so reversing the policy is not recommended since returning tax payments to colleges may not ensure the money is used to improve educational equity. [Bulman \(2022\)](#) and [Brown et al. \(2014\)](#) found that colleges often use endowment returns to become more selective or to accumulate wealth rather than enhance equity. Thus, the government could use the revenue to improve access to higher education and redesign the taxation to offer incentives for positive responses. These findings also suggest colleges are willing to expand enrollment to gain tax exemption status. Therefore, the policy could grant tax exemptions or deductions based on the proportion or amount spent from endowment assets, incentivizing colleges to improve service quality and equity.

Secondly, for nonprofit taxation policy in general, this paper identifies that nonprofits respond differently to taxation than for-profit organizations, thus, allowing the government to tax nonprofits without diminishing societal benefits. Crucially, nonprofits tend to maximize their service levels and social welfare and will be willing to respond to taxation by providing more public goods, even if it costs them more. Most government taxation or regulatory thresholds are based on the logic that larger and more capable organizations should pay more or do more. However, this logic may be unsuitable for nonprofits. If the rationale for nonprofit tax exemption is that they provide public goods, then larger and more capable nonprofits (conditional on also providing more public goods) might deserve even more generous tax benefits. The evidence in this paper also suggests that a well-designed tax structure can encourage nonprofits to respond in ways that align with desirable social outcomes. Though concerns about tax shifting do exist, since nonprofits care about their mission and social welfare, they may choose approaches that best preserve their values. Therefore, taxing nonprofits does not necessarily lead to unacceptable consequences. The overall social welfare implications depend on whether the government can use its tax revenues to address potential burden transfers due to tax shifting.

Principia College	479	479	377	788	N	N	N	N	N

Note: The student enrollment and endowment assets information were in 2016. Full-time equivalent (FTE) is calculated as the sum of full-time and one-third of part-time students. Endowment asset amounts are reported in nominal values. Tax status indicates whether a college is subject to the net investment income tax (NIIT) in a specific year. **Y** refers to being subject to the net investment income tax, while **N** refers to not being subject. The NIIT applies to colleges with over 500 students and more than \$500,000 in endowment assets per student.

Table A2: Estimated Net Investment Income Tax Payment

	Average Expenditure / Revenue / Payment (\$ Million)				Share of Invest Rev. to Total Rev.	Share of Est. Tax to Total Exp.	Share of Est. Tax to Total Rev.
	Total Expenditure	Total Revenue	Investment Revenue	Estimated NIIT			
Panel A: Student above 500, and per student Asset above 600K							
Princeton University	1,541	3,803	3,073	43.03	58.23%	2.79%	0.82%

Note: The distances from the endowment threshold are calculated as the amount/number/proportion of endowment/students needed to be increased or decreased in order to make a college meet the tax threshold to be exempted from the tax or a college below the thresholds to be subject to the tax. The average growth rates were averaged from 2010 to 2016. All monetary amounts are reported in nominal values.

Figure A1: Distribution of Endowment Assets Per-student

Note: The samples are private nonprofit colleges that reported in IPEDS and filed Form 990 every year from 2010 to 2022. Endowment assets per student are calculated as endowment asset values divided by full-time equivalent (FTE) students (with one part-time student taken into account as one-third of full-time students). Endowment asset amounts are reported in nominal values.

Figure A2: Tax Avoidance Behaviors: Robustness Check by Definitions of Treated Period

Note: The coefficients are estimated using equation (1). The error bars denote the 95% confidence interval. The samples are private nonprofit colleges that reported in IPEDS and filed Form 990 every year from 2010 to 2022, with a student population above 500 in 2016. FTE (full-time equivalent) is calculated as the sum of full-time and one-third of part-time students.

Figure A3: Tax Shifting Behaviors: Robustness Check by Definitions of Treated Period

Note: The coefficients are estimated using equation (2). The error bars denote the 95% confidence interval. The samples are private nonprofit colleges that reported in IPEDS and filed Form 990 every year from 2010 to 2022, with a student population above 500 in 2016. FTE (full-time equivalent) is calculated as the sum of full-time and one-third of part-time students.

Appendix B: Restricting Sample to Selective Colleges

B1 Empirical Design

A primary concern in the DD setting of the main analysis is the potential disparity between the treatment group (colleges taxed or near the tax threshold) and the comparison group, which typically consists of less wealthy and less selective institutions. This fundamental difference raises questions about the validity of the comparison group as a counterfactual for the treatment group.

To address this concern, I restrict the comparison group to institutions more closely resembling those in the treatment group. Beyond their wealth, most colleges subject (or potentially subject) to the NIIT are characterized by high selectivity and prestige. For instance, among the 41 colleges in our treatment group (including those taxed and those very close to the threshold), 32 are categorized as “most selective” in the Barron’s Selectivity Index, three are classified as “highly competitive,” and one is considered “very competitive.” The remaining five are categorized as “specialized institutions.” Furthermore, in the U.S. News Rankings, 32 of these colleges ranked in the top 50 (either of the ranking list of National Universities or Liberal Arts Colleges), with one ranked between 50-100 and another between 100-150.

It is reasonable to posit that colleges with similar levels of selectivity and prestige might react similarly to macroeconomic environments. These highly selective institutions typically compete with one another to attract students, and they tend to pursue similar admission strategies ([Smith et al., 2018](#)). Colleges with comparable reputations and academic rankings also tend to share similar financial metrics and management strategies ([Volkwein & Sweitzer, 2006](#)). Previous studies suggest that restricting comparisons to institutions with similar academic standing could provide a more reliable basis for analysis ([Stange, 2015](#); [Zhu et al., 2021](#); [Bennett, 2022](#)).

To construct more appropriate comparison groups, I link the dataset to the 2016 Barron’s Selectivity Index and U.S. News rankings (for both National Universities and Liberal Arts Colleges). I created two sub-samples: one restricting to institutions in Barron’s top three selectivity categories and another including those ranked in the top 100 by U.S. News in 2016.

Table B1 details the sample sizes in these sub-samples. It is important to note that while this approach restricts the comparison group to institutions more similar to the treatment group, it also excludes some treatment group institutions that are less selective and prestigious than their counterparts. This refined sample selection strategy aims to create a more comparable control group, addressing concerns about the uniqueness of the treated institutions and the potential lack of a reasonable counterfactual. By focusing on institutions with similar prestige and selectivity, we enhance the validity of our DD design, although we acknowledge the trade-off in sample size and the potential exclusion of some treated institutions.

Table B1: Number of Units in Each Sub-sample

Sub-sample	Number of Units	
	Treatment Group	Comparison Group
Tax Avoidance		
Main Results	17	752
Barrons Selectivity Index Above Very Competitive	16	268
US News' Ranking Top 100	14	108
Tax Shifting		
Main Results	24	752
Barrons Selectivity Index Above Very Competitive	20	268
US News' Ranking Top 100	19	108

B2 Empirical Results

B2.1 Tax Avoidance

Table B2 replicates the main results of colleges' manipulation behaviors related to student enrollment using our alternative, more selective samples. The findings suggest that colleges around the cutoff increased their FTE enrollment by 5.4% to 6.6%, closely aligning with our main estimate of 6.4%. This consistency across sample specifications strengthens our confidence in the robustness of these results. The decomposition results by enrollment status and education level also echo the main findings. Figure B1 demonstrates the dynamic effect based on the event study design, with the trajectory of the response aligning closely with the main results.

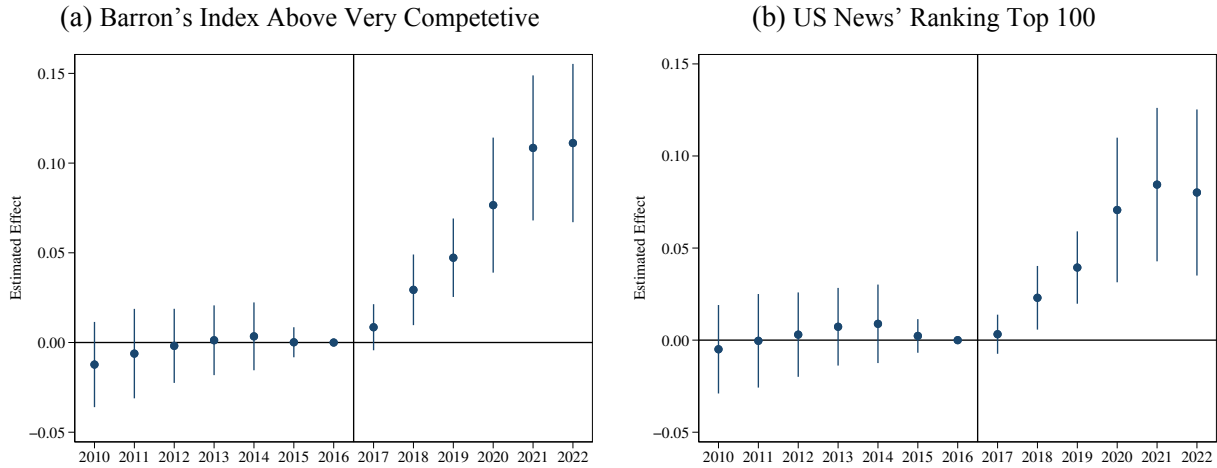

Table B2: Student Enrollment-related Tax Avoidance Behavior: Selective Colleges

	(1)	(2)	(3)	(4)	(5)
	Log FTE	By Enrollment Status		By Student Level	
	Enrollment	Full-time	Part-time	Undergraduate	Graduate
Panel A: Barron's Rank Above Very Competitive					
<i>Cutoff × Post</i>	0.076*** (0.019)	0.077*** (0.020)	0.024 (0.124)	0.068*** (0.024)	0.051 (0.187)
Observations	3,640	3,640	3,640	3,640	3,640
Baseline Mean (Thousand)	7.272	6.955	0.950	4.010	3.262
Panel B: US News' Ranking Top 100					
<i>Cutoff × Post</i>	0.057*** (0.020)	0.057*** (0.020)	0.064 (0.136)	0.045* (0.026)	0.119 (0.212)
Observations	1,560	1,560	1,560	1,560	1,560
Baseline Mean (Thousand)	7.988	7.630	1.072	4.274	3.714

Note: The coefficients are estimated using equation (1). Standard errors clustered at the institution level in parentheses. The outcomes are log students enrollment. The number of full-time equivalent (FTE) students is defined as the sum of full-time and one-third of part-time students. Panel A restricts the sample to those with Barron's Rank as most competitive, highly competitive, or very competitive. Panel B restricts the sample to those with US News Ranking among the top 100 in 2016.

Figure B1: Tax Avoidance Behavior: Log Number of FTE Students

Note: The coefficients are estimated using the event study version of equation (1). The error bars denote the 95% confidence interval. Samples are private non-profit colleges that reported in IPEDS and filed Form 990 yearly from 2010 to 2022, with a student population above 500 in 2016. Figure B1a restricts the sample to those with Barron's Rank as most competitive, highly competitive, or very competitive. Figure B1b restricts the sample to those with US News Ranking among the top 100 in 2016.

Table B3 examines endowment asset manipulation. Consistent with the main results, I find a null response in total endowment and across various asset categories. This consistency suggests our results are not driven by differences between highly and less selective institutions. Figure B2 illustrates the event study analysis, showing temporal patterns of endowment responses mirror our main analysis, reinforcing the robustness of our results across institutional profiles.

Figure B2a restricts the sample to those with Barron's Rank as most competitive, highly competitive, or very competitive. Figure B2b restricts the sample to those with US News Ranking among the top 100 in 2016.

B2.2 Tax Shifting

Table B4 presents a similar analysis focusing on tax-shifting behaviors. The results show a null effect on total spending and in most spending categories, consistent with our main findings. The only exception is the estimate of total spending on institutional grants. While the main result shows no significant impact on institutional grants, the subsample focusing on selective colleges demonstrates a 9% to 41% increase in grant spending ($p < 0.1$). However, it is important to note that due to the smaller sample size, these estimates are less precise. Figure B3 illustrates the dynamic effects based on the event study design. The Barron's Index sample shows a pattern very similar to the main findings, while the US News sample demonstrates a minor, non-significant negative trend in total spending after policy adoption.

Table B4: Expenditure-related Tax Shifting Behavior: Selective Colleges

	(1)	(2)	(3)	(4)	(5)	(6)	(7)

Note: The coefficients are estimated using equation (2). Standard errors clustered at the institution level in parentheses. The outcomes are the log expenditure by spending category. Column (1) is the total expenditure. Column (2) is the sum of instructional and academic support expenditures. Column (3) is the sum of research and independent operation expenditure. Column (4) is the public service expenditure. Column (5) is the institutional support expenditure, which includes spending on operational support, administrative services, and management. Column (6) is the sum of auxiliary facilities, hospital, and student service expenditure. Column (7) is the net institutional grant aid to students, including scholarships and fellowships. All dollars are adjusted by CPI and denoted in 2010 real dollars. Samples are private non-profit colleges that reported in IPEDS and filed Form 990 yearly from 2010 to 2022, with a student population above 500 in 2016. All Panels exclude colleges with endowment assets per student between \$400,000 and 600,000 in 2016 (i.e., only include the donut sample). Panel A restricts the sample to those with Barron's Rank as most competitive, highly competitive, or very competitive. Panel B restricts the sample to those with US News Ranking among the top 100 in 2016. The observation period is from 2010 to 2021.

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

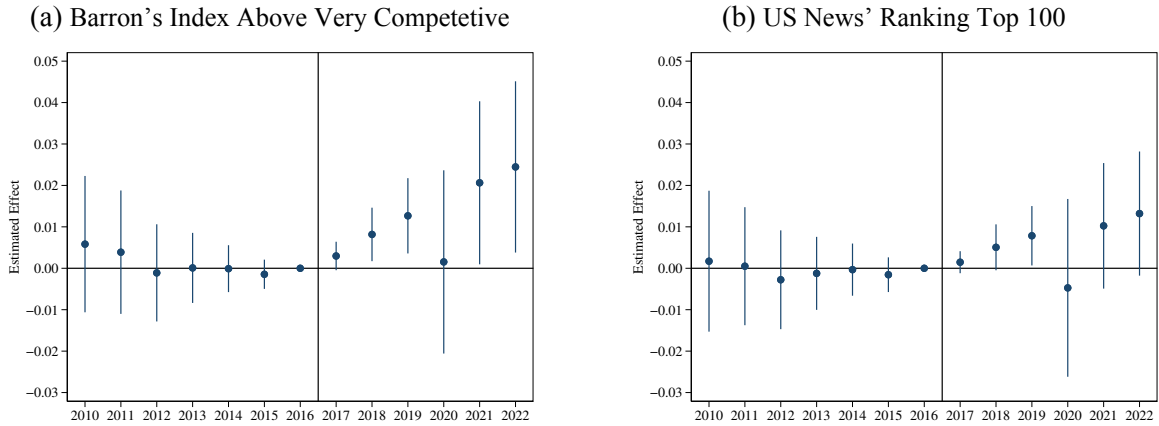

Figure B3: Tax Shifting Behavior: Log Total Expenditure

Note: The coefficients are estimated using the event study version of equation (2). The error bars denote the 95% confidence interval. Samples are private non-profit colleges that reported in IPEDS and filed Form 990 yearly from 2010 to 2022, with a student population above 500 in 2016. Figure B3a restricts the sample to those with Barron's Rank as most competitive, highly competitive, or very competitive. Figure B3b restricts the sample to those with US News Ranking among the top 100 in 2016.

Table B5 investigates responses in tuition and charges. The results indicate that taxed colleges increase listed undergraduate tuition by 1.8% to 2.7%, close to the main estimate of 2.4%. Figure B4 demonstrates the dynamic effects based on the event study design. Both samples show similar trends, though the US News sample exhibits a smaller magnitude of effect. The response in room & board charges shows some variation across samples. Results restricted to institutions with higher Barron's Selectivity Index demonstrate an increase in charges of 4.4% (close to the main estimate of 4.2%), while results based on top-ranking colleges show an insignificant 1.8% response.

Figure B4: Tax Shifting Behavior: Log Listed Undergraduate Tuition

Note: The coefficients are estimated using the event study version of equation (1). The error bars denote the 95% confidence interval. Samples are private non-profit colleges that reported in IPEDS and filed Form 990 yearly from 2010 to 2022, with a student population above 500 in 2016. Figure B4a restricts the sample to those with Barron's Rank as most competitive, highly competitive, or very competitive. Figure B4b restricts the sample to those with US News Ranking among the top 100 in 2016.

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

B2.3 Enrollment Composition

Table B6 explores the effects on student enrollment by race/ethnicity. In general, the results align well with the main findings. Tax avoidance behaviors lead to an increase in student enrollment across almost all racial/ethnic groups (with the exception of Black students in the US News subsample). Conversely, tax-shifting behaviors result in a significant decrease in Hispanic student enrollment. The US News sample additionally identifies a significant negative effect on Black student enrollment. These results from more selective subsamples largely corroborate our main findings, suggesting that the observed effects on enrollment composition are consistent across different institutional profiles.

Table B6: Student Enrollment-related Tax Avoidance and Shifting Behavior by Race/Ethnicity

Appendix C: Triple-Difference Design

C1 Empirical Strategy

In the main analysis, I use the DD framework to estimate colleges' tax avoidance and shifting behaviors. In the tax avoidance analysis, the treatment group consists of colleges near the asset threshold of the NIIT, while the comparison groups include those far away from the threshold. In the tax shifting analysis, I compare colleges subjected to the tax (treatment group) with those that meet the student threshold but not the asset threshold (the comparison group). However, in both settings, given the substantial difference between treatment and comparison groups, concern exists about whether they would have shared the same trend in the outcome variables. Despite the event study analysis demonstrating a parallel pre-treatment trend (at least conditional on the fixed effect), the concern of the DD setting still remains.

Hence, this study further applies a triple-difference (DDD) framework to test the robustness of the results. In the main analysis, I only included colleges that met the student threshold and separated the samples into treatment and comparison groups depending on the distance to the assets threshold. In the DDD design, I further introduce those colleges that do not meet the student threshold as additional comparison groups. The setup slightly differs between the tax avoidance and shifting analysis.

C1.1 Tax Avoidance

In the tax avoidance analysis, I compare the colleges around the assets threshold and those far away between those meeting the student threshold and those not. In other words, I compare two differences: (1) the difference between the cutoff sample (with endowment assets per student within \$400,000 to \$600,000 in 2016) and the non-cutoff sample within large colleges (with student enrollment greater than 500 in 2016); (2) the same difference but within small colleges (with student enrollment less than 500 in 2016). And then, I track the change in the gaps between these two differences across time. Specifically, I estimate the following equation:

$$Y_{it} = \alpha_0 + \beta_1 Large_i \times Cutoff_i \times Post_t \quad (C1)$$

$$+ \theta_i + Large_i \times \delta_t + Cutoff_i \times \zeta_t + Above_i \times \phi_t + \varepsilon_{it}$$

Where $Large_i$ is a dummy variable indicating that the colleges had a student population above 500 in 2016. $Cutoff_i$ is a dummy variable indicating that the colleges had endowment assets per student within \$400,000 and \$600,000 in 2016. The equation includes the student population by year fixed effect ($Large_i \times \delta_t$), which accounts for the potential difference in trends between large and small colleges. Similarly, the inclusion of the distance to the cutoff status by year fixed effect ($Cutoff_i \times \zeta_t$) accounts for the potential difference in trends between those colleges that have similar levels of wealth and those not. θ_i is the institution fixed effect, which absorbs the interaction term of $Large_i \times Cutoff_i$. These three terms stand for the full interactions to establish the DDD setting. Similar to the equation (1), the specification includes the above-cutoff-status-by-year fixed effects ($Above_i \times \phi_t$) to account for potential differences in trends between those subject and those not subject to the tax. The key parameter is β_1 , which indicates the behavioral response of colleges that have the motivation of tax avoidance.

The empirical assumption of the DDD is that the difference in outcomes between “large, around assets cutoff” and “large, not around assets cutoff” colleges would have followed the same trend as the difference between “small, around assets cutoff” and “small, not around assets cutoff” colleges in the absence of the policy. This assumption might be valid as the primary factors determining colleges’ enrollment and finance metrics would be their student body and available resources.

C1.2 Tax Shifting

In the tax shifting analysis, I separate colleges into four groups by both the student and assets threshold. Colleges meeting the student threshold (with student enrollment greater than 500 in 2016) are categorized as large and small otherwise. Colleges meeting the asset threshold (with endowment assets per student above \$500,000 in 2016) are categorized as wealthy and non-wealthy otherwise. As demonstrated in Figure 1a, this categorization groups colleges into four quadrants, with the upper right corner denoting the treatment group.

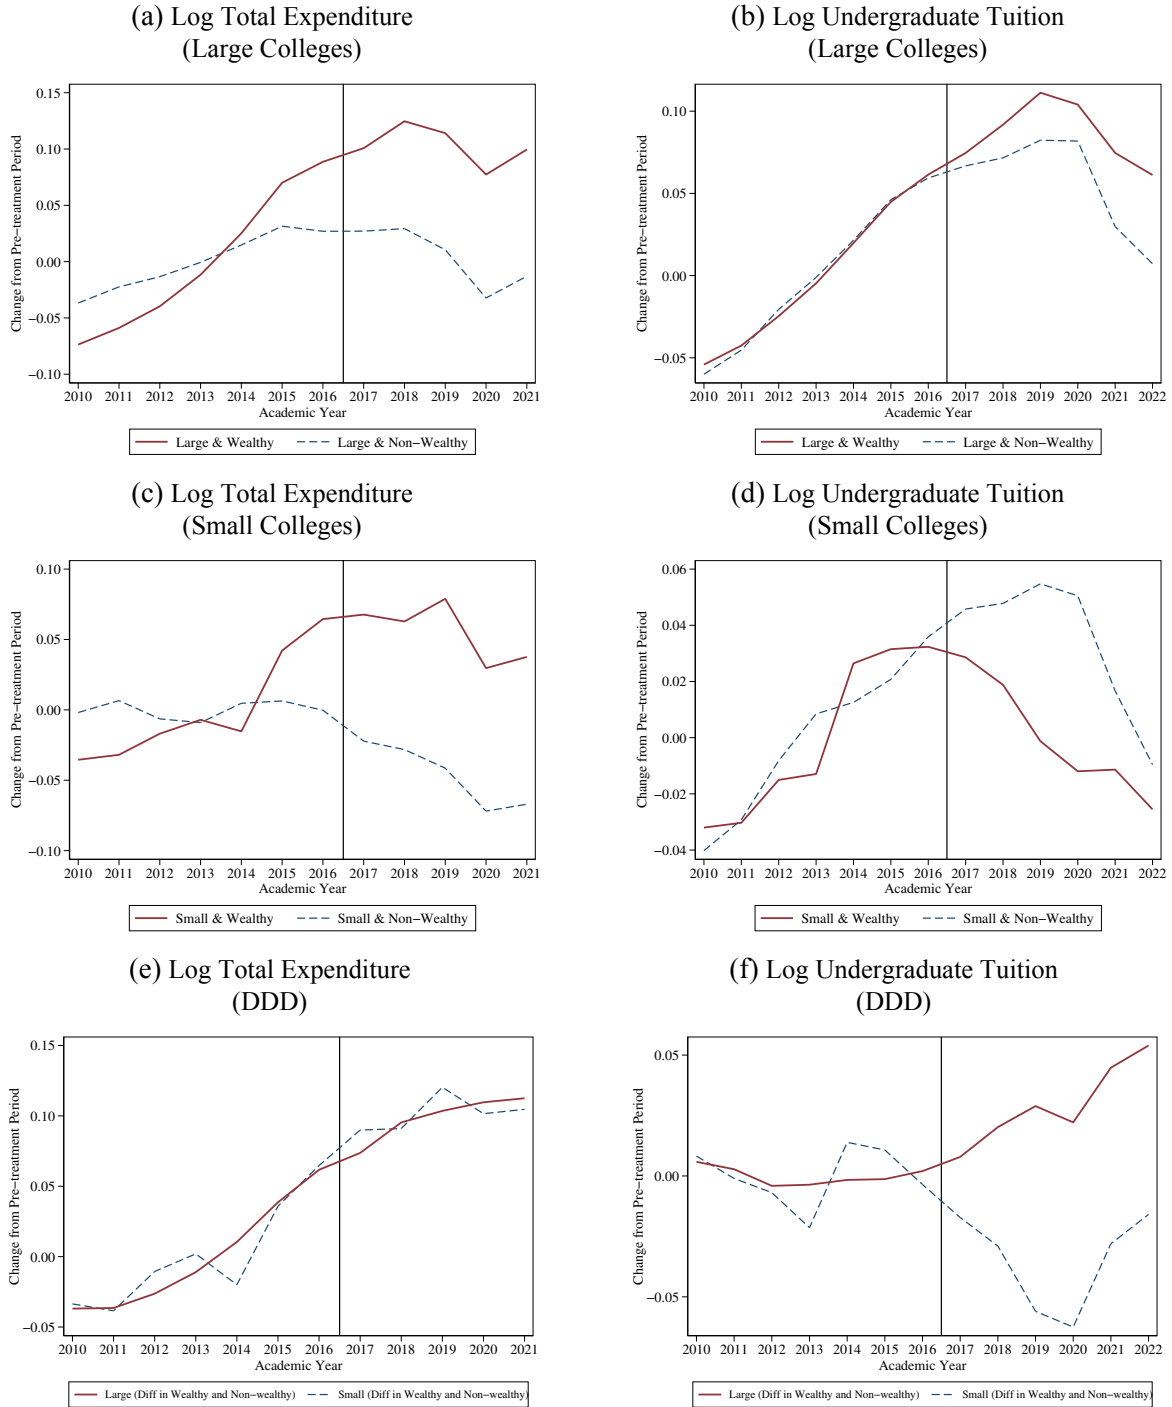

The basic idea of the DDD setting is to compare the changes in the gap between large wealthy and large non-wealthy colleges as well as the gap between small wealthy and small non-wealthy colleges. This analysis consists of all colleges (including those that unmet the student threshold) but still excludes those around the cutoff to prevent confounding from tax avoidance behaviors. Specifically, I estimate the following equation:

$$Y_{it} = \alpha_0 + \beta_1 Large_i \times Wealthy_i \times Post_t + \theta_i + Large_i \times \delta_t + Wealthy_i \times \zeta_t + \varepsilon_{it} \quad (C2)$$

Where $Large_i$ is a dummy variable indicating that the colleges had a student population above 500 in 2016. $Wealthy_i$ is a dummy variable indicating that the colleges had endowment assets per student above \$500,000 in 2016. The equation includes the student population by year fixed effect ($Large_i \times \delta_t$), which accounts for the potential difference in trends between large and small colleges. Similarly, the inclusion of asset size by year fixed effect ($Wealthy_i \times \zeta_t$) accounts for the potential difference in trends between wealthy and non-wealthy colleges. θ_i is the institution fixed effect, which absorbs the interaction term of $Large_i \times Wealthy_i$. These three terms stand for the full interactions to establish the DDD setting. The key parameter is β_1 , which indicates the impact of policy on the colleges subject to the NIIT.

The empirical assumption of the DDD setting is that the difference in outcomes between “large, wealthy” and “large, non-wealthy” colleges would have followed the same trend as the difference between “small, wealthy” and “small, non-wealthy” colleges in the absence of the policy. In other words, the DDD design assumes that the gap between wealthy and non-wealthy colleges would be the same between colleges with various student sizes. This assumption might be valid as the primary factors determining colleges’ finance metrics would be their service population and available resources. This paper further evaluates the assumption by examining the pre-treatment parallel trend. Specifically, while “large, wealthy colleges” (treated group) hold a faster growth rate in expenditure than the “large, non-wealthy colleges” (see Figure C1a), the same pattern appears in the comparison between “small, wealthy colleges” versus “small, non-wealthy colleges” (see Figure C1c). Figure C1e compares the gap in two paired comparisons and shows the same trend over time.

Figure C1: Tax Shifting: Trend in Total Expenditure and Tuition

Note: The samples are private nonprofit colleges that reported in IPEDS and filed Form 990 every year from 2010 to 2022 and exclude colleges with endowment assets per student between \$400,000 and 600,000 in 2016 (i.e., only include the donut sample). The horizontal axis denotes the year (using the start year of the academic/fiscal year). The vertical axis denotes the percent change in the outcome variable from the pre-treatment period. The vertical line denotes the year of policy implementation. Large (small) colleges are colleges with more (less) than 500 students in 2016. Wealthy (non-wealthy) colleges are colleges with more (less) than \$500,000 endowment assets per student (in nominal values) in 2016.

This paper employs DD in the primary setting while using DDD as a robustness check. The choice of the preferred specification involves a trade-off between bias and precision. While the DDD framework is better suited to correct the bias of comparing colleges with different asset levels, it necessitates the introduction of a comparison group of small but wealthy colleges. Most of these colleges are arts or medical schools. Due to their small student population and significant assets, they typically experience frequent and substantial fluctuations in spending. This setting, therefore, introduces more noise to the estimation and leads to larger standard errors.

C2 Empirical Results

C2.1 Tax Avoidance

The DDD results of the student enrollment-related tax avoidance align with the main findings, though with larger standard errors. Table C1 demonstrates that colleges around the cutoff increase their FTE enrollment by 16% after the policy implementation, despite the estimate being non-significant. The event study results in Figure C2a show a good pre-treatment common trend and a clear pattern of increase in enrollment among the “large and around cutoff” group, despite all estimates being non-significant. The noisier estimates are likely due to fluctuations in student enrollment among smaller colleges. Despite this limitation, the pattern in student enrollment among affected colleges is still evident and aligns with the main findings.

Table C1: Student Enrollment-related Tax Avoidance Behavior: DDD Setting

	(1)	(2)	(3)	(4)	(5)
	Log FTE	By Enrollment Status		By Student Level	
	Enrollment	Full-time	Part-time	Undergraduate	Graduate
<i>Large × Cutoff × Post</i>	0.181 (0.134)	0.198 (0.162)	0.095 (0.139)	0.066 (0.100)	0.213 (0.248)
Observations	11,661	11,661	11,661	11,661	11,661
Baseline Mean (Thousand)	4.928	4.715	0.639	2.678	2.250

Note: The coefficients are estimated using equation (C1). Standard errors clustered at the institution level in parentheses. The outcomes are log students enrollment. The number of full-time equivalent (FTE) students is defined as the sum of full-time and one-third of part-time students.

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

Figure C2: Event Study Estimates: Avoidance Behavior

Note: The coefficients are estimated using the event study version of equation (C2). The error bars denote the 95% confidence interval. The samples are private nonprofit colleges that reported in IPEDS and filed Form 990 every year from 2010 to 2022, and exclude colleges with endowment assets per student between \$400,000 and 600,000 in 2016 (i.e., only include the donut sample).

Table C2 explores the manipulation behaviors on endowment assets. The results demonstrate a 12% non-significant drop in total endowment for colleges with motivation for tax avoidance. Despite the non-trivial point estimate, the event study result in Figure C2b shows no clear pattern of a drop in asset values after the policy implementation. The overall findings still align with the main results.

Due to the increase in enrollment and unchanged endowment assets, the results show a drop in endowment assets per student (see Column (2) in Table C2 and Figure C2c). Overall, the tax avoidance findings from the DDD setting corroborate the main findings.

Table C2: Tax Avoidance Behavior on Student Enrollment

	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
	Log Endowment		By Restricted Status		By Category

Note: The coefficients are estimated using equation (C1). Standard errors clustered at the institution level in parentheses. The outcomes are log endowment assets. All dollars are adjusted by CPI and denoted in 2010 real dollars. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

C2.2 Tax Shifting

The DDD results of the tax shifting response on total expenditure are quite similar to the DD estimations. Table C3 demonstrates that taxed colleges underwent an insignificant 0.2% increase in their total expenditure after the policy intervention (see Column (1)). There are also no negative responses for any of the spending categories.

Table C3: Expenditure-related Tax Shifting Behavior: DDD Setting

	(1)	(2)	(3)	(4)	(5)	(6)	(7)
	Log Expenditure						
	Total	Instruction	Research	Public Service	Institution Support	Auxiliary Facilities	Institution Grant
<i>Large × Wealthy × Post</i>	0.002 (0.043)	0.025 (0.043)	0.029 (0.054)	0.140** (0.059)	0.102 (0.108)	0.042 (0.047)	0.249 (0.411)
Observations	11,004	11,004	11,004	11,004	11,004	11,004	11,004
Baseline Mean (Million)	1,524	478	222	28	121	459	123

Note: The coefficients are estimated using equation (3). Standard errors clustered at the institution level in parentheses. The outcomes are the log expenditure by spending category. Column (1) is the total expenditure. Column (2) is the sum of instructional and academic support expenditures. Column (3) is the sum of research and independent operation expenditure. Column (4) is the public service expenditure. Column (5) is the institutional support expenditure, which includes spending on operational support, administrative services, and management. Column (6) is the sum of auxiliary facilities, hospital, and student service expenditure. Column (7) is the net institutional grant aid to students, including scholarships and fellowships. All dollars are adjusted by CPI and denoted in 2010 real dollars. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

The event-study estimation reassures the findings. Figure C3 demonstrates non-significant estimates for all the pre-intervention periods, showing a good common trend. The results also suggest a null effect on spending change after the policy intervention.

Figure C3: Event Study Estimates: Tax Shifting Behavior on Total Expenditure

Note: The coefficients are estimated using the event study version of equation (C2). The error bars denote the 95% confidence interval. The samples are private nonprofit colleges that reported in IPEDS and filed Form 990 every year from 2010 to 2022, and exclude colleges with endowment assets per student between \$400,000 and 600,000 in 2016 (i.e., only include the donut sample).

The results on tuition hikes align with the DD results but with larger estimates. Table C4 finds that taxed colleges underwent a 10% increase in undergraduate tuition ($p < 0.01$, see Column (2)), 5% increase in graduate tuition ($p < 0.1$, see Column (3)), and 6% increase in room and board charge ($p < 0.01$, see Column (4)). Despite the larger magnitude, the 95% confidence intervals overlap with the DD estimates. The event-study estimates (see Figure C4), confirm the parallel trend in the pre-intervention period and show that the tuition has gradually increased over time.

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

Figure C4: Event Study Estimates: Tax Shifting Behavior

Note: The coefficients are estimated using the event study version of equation (C2). The error bars denote the 95% confidence interval. The samples are private nonprofit colleges that reported in IPEDS and filed Form 990 every year from 2010 to 2022, and exclude colleges with endowment assets per student between \$400,000 and 600,000 in 2016 (i.e., only include the donut sample).

Figure C1 provides insight into the inconsistency in effect sizes between the DD and DDD models. As demonstrated in Figure C1b, colleges that are large and wealthy (subjected to the tax) show a parallel trend in tuition with colleges that are large but non-wealthy (the comparison group in the DD model) prior to the policy. However, the treatment group increased their tuition relatively more than the comparison group after the policy was effective. Despite the good pre-treatment common trend implying that large but non-wealthy colleges could serve as a good counterfactual, concerns remain about whether the common trend assumption would continue to hold true. Particularly, the pandemic might serve as a potential factor that affects the two groups differently.

This concern is backed up by evidence from the second control group from the DDD model. Figure C1d demonstrates that small but wealthy colleges and small and non-wealthy colleges also possess parallel trends prior to the policy, although these groups are more fluctuate due to their small nature. However, small but wealthy colleges show a larger drop in their tuition level during the pandemic period. One explanation could be that they are more able to use their assets to support students with a lower tuition level during hard times. The suspicion is aligned with previous studies' perspective that endowment assets could serve as the "rainy day fund" (Baum & Lee, 2019; Rosen & Sappington, 2019). In the DDD model, the response of small wealthy colleges could serve as

a counterfactual for how large wealthy colleges would respond to the macro environment. Since the DDD model predicts that the treated colleges should have been able to control their tuition at a lower level as the small wealthy colleges did, the model produces a causal estimate of a larger relative increase in tuition for the treated colleges. Whether small wealthy colleges could serve as a better counterfactual for the treatment group than large non-wealthy colleges is untestable. Therefore, this paper presents the DD estimate as the lower bound while the DDD estimate as the higher bound.

Overall, the DDD estimates are generally aligned with the DD results. The evidence suggests that taxed colleges do not respond to the taxation by cutting spending but might increase tuition to shift the burden.

Appendix D: Methodology Details on Permutation Test for SCM

This paper utilize the Synthetic Control Method (SCM) to examine the treatment effect on individual institution. The conventional SCM only offer point estimates but not inference statistics. To obtain the inference statistics, this paper obtains the distribution of the estimates using a permutation test. Specifically, I perform the following steps:

Step 1: Applying SCM to placebo units:

In this step, I take each of the units in the donor pool and perform the SCM (using equation (3)). For the analysis on tax avoidance, there were 800 colleges in the donor pool; and in the tax shifting analysis, there were 752 colleges in the donor pool (see Table C1). In this permutation test, the units in the treatment group are excluded from the analysis. The practice in this step provides 800 (752) placebo estimates on each of the single units in the donor pool.

Table C1: Number of Units in Each Analysis

Analysis	Number of Units	
	Treatment Group	Donor Pool
Tax Avoidance	17	800
Tax Shifting	24	752

Step 2: Estimating placebo treatment effects:

In this step, I randomly select N placebo estimates from the previous step and calculate the average treatment effect at each time period ($\bar{\beta}_t$; using equation (C1)). The number N is defined with the actual number of treated units. For example, in the tax avoidance analysis, I randomly selected 17 placebo estimates to take the average; and in the tax shifting analysis, the number would be 24. The procedure is then repeated 1,000 times, resulting in a distribution of the estimates.

$$\bar{\beta}_t = \frac{1}{N} \sum_{i=1}^N \beta_{it} \quad (C1)$$

By this stage, I can already compare the actual estimates with the placebo ones to obtain the permutation p-values (for a single time period). Figure C1 demonstrates the distribution of the placebo estimates placed along with the actual estimates. These placebo estimates serve as the potential distribution of the estimated $\bar{\beta}_t$ in the absence of the policy. If the actual estimate is located at the range out of most (such as 95%) of the placebo estimates, then the estimated policy effect is likely not due to random. For the estimation of the impact of tax avoidance behavior on student enrollment, the results suggest that the actual estimate is located at the upper bound of the placebo estimates, especially in the latter year (see Figure C1a). For the estimation of the impact of tax-shifting behavior on tuition revenue, the actual estimate is also located at the upper bound of the placebo estimates (see Figure C1d).

Figure C1: SCM Permutation Test: Dynamic Treatment Effect

Step 3: Calculating permutation p-value for ATT:

The former step obtains the dynamic treatment effect for the placebo units. I then apply equation (C2) to compute the ATT for the entire post-treatment period.

$$ATT = \frac{1}{T - T_0 + 0.5} \left(0.5 \times \overline{\beta_{t=T_0}} + \sum_{t>T_0}^T \overline{\beta_t} \right) \quad (C2)$$

Figure C2 demonstrates the distribution of placebo estimates (the histogram) and the location of the actual ATT (vertical line). The permutation p-value is calculated by counting the number of placebo estimates in excess of the actual estimate. In the case of tax avoidance impact on enrollment, the permutation p-value is 0.008 as only 8 out of 1000 placebo ratio excess the actual value (see Figure C2a). Table C2 to C5 report the ATT and permutation p-value of each variable.

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

Table C5: Enrollment, Tuition, and Charge-related Tax Shifting Behavior: SCM Results

	(1)	(2)	(3)	(4)	(5)	(6)
	Log FTE	Log Listed Price			Log Total Revenue	
	Enrollment	Undergrad Tuition	Graduate Tuition	Room & Board	Tuition	Auxiliary
<i>ATT</i>	0.040**	0.035*	0.016	0.018***	0.069**	-0.013
Permutation p-value	0.040	0.050	0.155	0.009	0.010	0.254
Range	[-0.14,0.21]	[-0.05,0.08]	[-0.29,0.17]	[-0.14,0.18]	[-0.04,0.27]	[-0.65,0.38]

Note: The *ATT* are estimated using equation (C2). The permutation p-values are estimated using Step 3 in Appendix C. Range denotes the minimum and maximum single-institution treatment effect.

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

Step 4: Calculating permutation p-value for single unit:

To estimate the permutation p-value for single institution, I follow the approach outlined in [Abadie et al. \(2010\)](#) to compute the post/pre mean squared prediction error (MSPE) ratio using the following equation:

$$MSPE\ ratio = \frac{\frac{1}{T - T_0} \sum_{t > T_0}^T (\bar{\beta}_t)^2}{\frac{1}{T_0 - 1} \sum_{t < T_0}^{T_0 - 1} (\bar{\beta}_t)^2} \quad (C3)$$

Next, I compared the ratios of the actual estimate to the placebo estimates. The permutation p-value is calculated by counting the number of placebo post/pre-MSPE ratios in excess of the actual ratio. The level of significance of each institution is noted in the Figures 4 and 7 in the manuscript.

Appendix E: Estimation Net Benefit of Enrollment Expansion

This section estimates the net benefit derived from the enrollment expansion due to tax avoidance behavior. The estimation here is primarily based on the full-time undergraduate students as this group is the major driver of the enrollment effect. I perform the following steps to estimate the net benefits:

Step 1: Estimated the increase in college degree holders

Based on the SCM estimation, the 17 colleges around the tax threshold collectively increased their full-time undergraduate enrollment by 9,623 as of 2022. Table E1 reports the estimation for each college. Applying the degree completion rate at these colleges, this increase in enrollment could eventually result in an additional 8,799 college degree holders.²⁹

Step 2: Obtained the net benefit of a college degree from prior studies

Previous studies have estimated the net personal benefit of earning a college degree to range from \$250 thousand to \$625 thousand (Hill et al., 2005; P. Taylor et al., 2011; Trostel, 2015), while the net social benefit falls between \$350 thousand and \$600 thousand (Hill et al., 2005; Edelson, 2016; Trostel, 2015). Combining the upper (lower) bounds of these estimates yields a total of \$1,225 (\$600) thousand. The estimations of individual benefits primarily hinge on the increase in earnings attributable to the degree, deducted tuition costs, and forgone earnings during college. Conversely, estimations of societal benefit primarily rely on the tax revenue accrued by the government due to increased labor earnings, net of government investment in higher education.

Step 3: Estimated the premium in return for sample college to less selective colleges

The increase in degree holders among these colleges might not be “additional.” It is possible that these students could have enrolled in another college had these colleges not expanded their access. Therefore, I assume that the expansion in enrollment access essentially “moves up” stu-

²⁹The average degree completion rate within 150% of normal time (i.e., 6 years) at these colleges is 88%, ranging from 65% to 97%. The estimation of degree holders is based on applying the degree completion rate in a specific college to the estimate of increased enrollment in the same college.

Table E1: Estimation of Net Benefit from Enrollment Expansion

	Barron's Ranking	Increase in FT Undergrad	Average Degree Completion Rate	Increase in Bachelor Degree	Estimate Net Benefit (\$ Million)
University of Chicago	Most competitive	1,695	0.956	1,620	65.118
Emory University	Most competitive	1,481	0.900	1,333	53.572
Northwestern University	Most competitive	941	0.965	908	36.505
Washington University in St Louis	Most competitive	872	0.937	817	32.857
University of Pennsylvania	Most competitive	741	0.961	712	28.609
Duke University	Most competitive	701	0.966	677	27.234
Colby College	Most competitive	538	0.880	474	19.043
Middlebury College	Most competitive	499	0.935	467	18.781
Vassar College	Most competitive	482	0.920	443	17.803
Berry College	Very competitive	457	0.647	296	8.345
Hamilton College	Most competitive	357	0.924	330	13.259
Davidson College	Most competitive	288	0.916	264	10.593
Trinity University	Highly competitive	246	0.758	187	7.502
Claremont McKenna College	Most competitive	139	0.913	127	5.088
Wabash College	Highly competitive	119	0.753	90	3.607
Bryn Mawr College	Most competitive	67	0.826	56	2.240
Mount Sinai School of Medicine	Special	0.09	N/A [†]	0	0.000
Total		9,623		8,799	350

Note: The Barron's Ranking is obtained from Barron's Profiles of American Colleges, which categorizes colleges into seven categories: most competitive, highly competitive, very competitive, competitive, less competitive, noncompetitive, and special (usually art or medical schools). The increase in full-time undergraduate enrollment is measured as of 2022. The estimates are retrieved from equation (C1). The average degree completion is measured as the proportion of bachelor's degree-seeking students who completed a bachelor's degree within 150 percent of the normal time (i.e., six years). The data is as of 2022 (calculated using the 2016 enrollment cohort). The increase in bachelor's degrees is calculated as the product of an increase in enrollment and average degree completion rate. For colleges of most competitive and highly competitive, the net benefit is estimated as 6.7% of the average personal and societal net benefit (i.e., \$600 thousand) of college degrees. For colleges that are very competitive, the net benefit is estimated as 4.7% of the average personal and societal net benefit (i.e., \$600 thousand) of college degrees.

[†] Mount Sinai School of Medicine does not report the degree completion data in the IPEDS.

dents from a less selective college to a more selective one instead of creating a new enrollment. Previous studies have widely established that the premium of attending a selective or elite college would exceed that of attending less selective ones (Kapur et al., 2016; Witteveen & Attewell, 2017; S. D. Zimmerman, 2019; Carnevale et al., 2022). Particularly, as demonstrated in Table E1, the majority of colleges engaged in tax avoidance behavior are categorized as most, highly, or very competitive.

I estimate the benefit of the enrollment expansion in these colleges by assuming the individual counterfactually attends a one-level lower college in Barron's Selectivity Index.³⁰ Specifically, for colleges categorized as most or highly competitive (tier 1 or 2), I assume that students would have

³⁰The categorization is retrieved from Barron's Profiles of American Colleges. The categorization is primarily based on "college selectivity"—computed with high school performance (ranking and GPA), standardized exams, and the admission rate. It categorizes colleges into seven categories: most competitive, highly competitive, very competitive, competitive, less competitive, noncompetitive, and special (usually art or medical schools).

attended very competitive colleges (tier 3) if the colleges had not expanded their access. For colleges categorized as very competitive (tier 3), I assume that students who have attended competitive (tier 4) colleges instead. Notice that I combined the groups of most and highly competitive (tier 1 and 2) as previous studies estimated the college return based on this categorization combined the two groups and did not provide a breakdown estimation (Witteveen & Attewell, 2017).

Witteveen & Attewell (2017) estimates the earning return from most or highly competitive colleges to be 6.7% higher than degrees from very selective colleges in the short run (4 years) and 11.3% higher in the long run (10 years). Besides, the earning return from very selective colleges is 4.7% higher than attending competitive colleges in the short run and 2.1% in the long run. I treat the percentage increase in the earnings for a higher level relative to a lower level college as the premium of attending a more selective college. Then, I define the net benefit of each additional college degree granted from these colleges to be the selective premium multiplied by the estimated total personal and societal net benefits.

Step 4: Calculated the total net benefit

Combining the above statistics, I calculated the total net benefit in each college using the below formula:

$$NetBenefit_{ij} = IncreaseEnrollment_i \times CompletionRate_i \times SelectivePremiums_j \times AvgNetBenefit \quad (E1)$$

Where the net benefit of college i of selective category j is the product of the increase in degree holders ($IncreaseEnrollment_i \times CompletionRate_i$), the percentage of increase in expected earning relative to less selective colleges ($SelectivePremiums_j$), and the estimated average net personal and society benefits of a college degree ($AvgNetBenefit$). $SelectivePremiums_j$ ranges from 2.1% to 11.3% depending on the selectivity of the colleges and whether the estimation is based on the short run or long run. $AvgNetBenefit$ is obtained from previous studies, ranging from \$600 to \$1,225.

Table E1 reports the most conservative estimates based on the lowest selective premiums and total net benefits. The sum of all colleges leads to a total net benefit of \$350 million. Figure E1 illustrates the ranges of estimation based on different assumptions. The estimates range from \$350 million to \$1,300 million.
